Update
Move data from CACP Calculator v3.0

Instructions

Welcome to Clean Air-Cool Planet's Greenhouse Gas Inventory Calculator. These spreadsheets will assist you in calculating the greenhouse gas emissions (CO_2, CH_4, N_2O, HFC and PFC, SF_6, and others) for your campus. It calculates emissions for each year 1990-2020 and provides summary information regarding the institution's emissions.

The directions below are designed to supplement the text component of the Clean Air-Cool Planet Emissions Inventory Toolkit. While the directions below are adequate to use the spreadsheets, we recommend that you read the toolkit to build an understanding of how they work.

Before making any changes or entering data, make a copy of this file (unless you have it on a CD) to use and save the original to refer to in the event that the copy is altered. If you are upgrading from v3.0, click the "Update" button above to move your data from the old sheets to this one. Next, fill in the name of your Institution and contact information in the box above. This will automatically update all of the sheets with your information. Cells in **GREEN** are input cells, enter your data here. Cells in **BLUE** are emissions factors, change these only if you understand what you are changing and have more accurate emissions factors for your school. White and Yellow cells should not be changed.

Navigation
The spreadsheet was designed for ease of use and transparency of calculation. The worksheet titled **Spreadsheet Map** contains a diagram of all the sheets in the calculator. Clicking on a sheet there will link you directly to the worksheet. Likewise, each worksheet has a link to the **Spreadsheet Map** located in the upper left corner. Thus although there are many sheets in this toolkit, each can be reached with only two clicks (the first to the spreadsheet map and the second to the sheet of choice). You can also enable the "Web" toolbar in Excel (View -> Toolbars -> Web) and use the forward and back arrows. Throughout the Calculator, there are small red triangles in certain cells. These cells contain notes that assist you in understanding the function of that particular cell or worksheet. To view these notes, place the mouse over the cell and the note will appear. At the bottom of every column is a gray row that explains the source of the data in that column. In some cases the source will be a government report, while in other cases it will be a formula explaining how the numbers were generated. If the source is another sheet, the cell will be a link to that sheet.

Emissions Calculator
There are five modules to the calculator:

1) ***Inputs Module.*** This module has two related worksheets: Inputs and the associated Commuter Inputs. Emissions-related data (i.e. fuel and electricity use, transportation) for your campus will be entered in the Inputs and Commuter Inputs Worksheets ONLY. All of the summary sheets will be updated when you enter data on the inputs sheets.

2) ***Summary Module***. This module takes the data from the Inputs & Commuter Inputs Worksheets and calculates emissions and generates graphs.

3) ***Project Module*** This module will assist you in developing an emissions estimate for a project or event. For example, if you wanted to estimate the emissions reduction associated with an increase in carpooling, the project module facilitates those calculations.

4) ***Emission factors Module.*** This module is where most of the number crunching takes place. These sheets develop emission factors using data from various government sources. If you want to know where the emission factors come from, explore the emission factors sheet for that sector.

5) ***Reference Module.*** This module includes this introduction sheet, a reference sheet that lists all the sources of emissions factors and methodologies, a glossary of terms, and a troubleshooting guide.

Use the spreadsheet map to explore!

Spreadsheet Map

This page lists all of the worksheets in the Clean Air - Cool Planet Greenhouse Gas Emissions Calculator. To visit a page, click on it or scroll through the tabs at the bottom of the excel window. Each worksheet has a link to this page in the top left corner, so any sheet can be accessed from any other sheet in two clicks (one to this sheet, the second to the desired sheet). There are three modules to this calculator: data from the institution are entered in the two "Inputs" sheets, the results are displayed and analyzed in the "Summary" sheets, and the calculations and emission factors are visible in the "Emission Factors" sheets. Arrows show the flow of data between sheets.

This graph is an example of your data to assist in choosing which years to display

On this worksheet: Summary information from an inventoried year, a pie chart showing a breakdown of sources, and a graph displaying the amounts of each gas emitted.

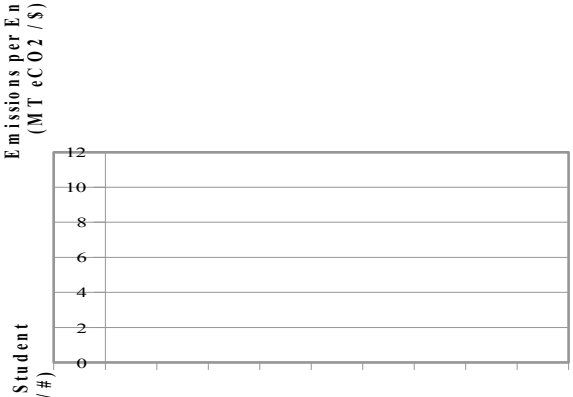
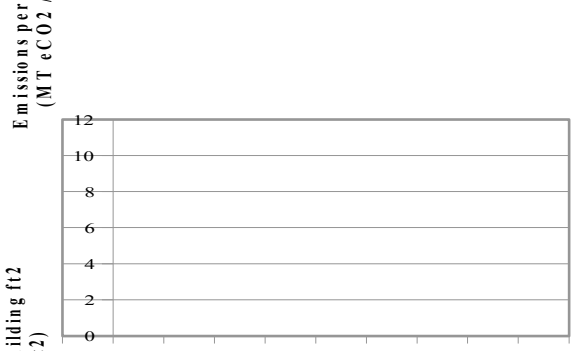
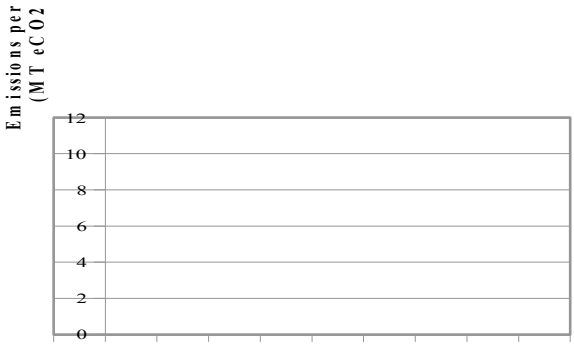
Emissions per operating dollar estimates the overall emissions efficiency of the institution. For every dollar that is spent, a certain amount of emissions are released.



Emissions per energy dollar estimates the overall emissions efficiency of the institution's energy production. For every dollar that is spent on energy, a certain amount of emissions are released.



Emissions per student normalizes the total emissions estimates by the size of the student body.



Emissions per square foot of building space is another estimate of the overall emissions efficiency of the institution.

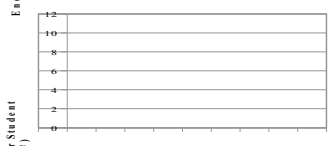
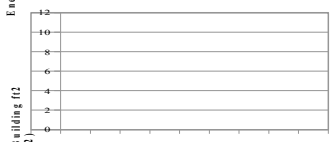
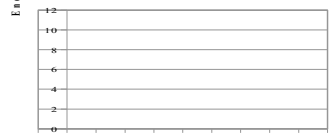
Energy use per operating dollar estimates the overall energy efficiency of the institution. For every dollar that is spent, a certain amount of energy is used. This plot tracks how that use has changed over time.



Energy use per energy dollar estimates the overall economic efficiency of the institution's energy production. Cheaper power will result in more energy per dollar spent.



Energy Use per student normalizes the total energy use estimates by the size of the student body.



Energy use per square foot of building space is another estimate of the overall energy efficiency of the institution.

On this Worksheet: This spreadsheet facilitates estimation of emissions from a single 'event' or project. Enter data into the green input cells. For example, if you wanted to estimate the impact of a project that reduced electric use by 1000 kWh, simply enter 1000 in the green "Purchased Electricity" input box. Summary data will be provided on the Project_Summary sheet.

Troubleshooting

If you get the message "*The cell or chart you are trying to change is protected and therefore read only*.

Solve it: In order to reduce accidental changes to the spreadsheets, they have all been 'protected' again change (except the input cells). If you are sure that you want to change a protected cell (or alter a graph put the arrow over 'Protection' in the tools menu and choose 'Unprotect Sheet." Be sure to turn protectio back on after you make the change to eliminate any accidental changes.

If you See "###" where you think there should be numbers:

Solve it: There is a number that is too big to fit within the column – make the column bigger by draggi one of its borders wider (at the top by the row of letters). You may need to disable protection (see above).

If labels on a graph are jumbled on top of one another and unreadable:

Solve it: Double click slowly on the label that needs to be moved, when a box has appeared around it, dra it to the desired position. You may need to turn off protection (see above) to alter the graph. You can al change the type or format of the graph to fit your needs. Be sure to not change the "source dat information.

If there are labels on graphs that do not apply to your institution:

Solve it: You can simply click slowly on the label that does not apply (i.e. if your school has no animal and press delete when the label is highlighted. This deletion is permanent, so be sure the label is not neede

To the top

Helpful Hints

A "-" in a cell means that it contains a formula, but that you have not entered data it needs. If you see a where you think there should be a number, then double check your inputs.

To keep a row heading (i.e. fuel type or year) in view as you scroll to the right, click on the column to t right of the row heading and then choose "Freeze Panes" from the Window menu. The row headings w disappear

To surf through the spreadsheets as if they were a series of web pages, enable the "Web" Toolbar in the Menu and use the forward and back buttons. Going back does NOT undo any changes that have been m (click on the Edit menu to undo).

Once all the data has been entered, print a copy of the inputs sheet for your records, and in case of comp troubles.

The Internet links in the spreadsheets are active; you can click on them to open the referenced web page

To the top

Changing/Adding Emissions Coefficients

If the institution uses fuels or has other sources of emissions that are not already included in the sprea you will need to add them. There are two steps to this process: changing the name, and then updati emissions factors for the new fuel. Several sectors (on-campus stationary sources, transportation, an etc.) have emission sources titled "Other." These columns are for you to add any additional sources th unique to your school. Change the name of the fuel/animal/refrigerant on the Inputs sheet, at the top appropriate column. Changing the name of the source will update the rest of the sheets. After changi of the fuel types (except refrigerants) the emissions factors will also need to be updated. After you c the name on the Inputs sheet, the "EF_" sheet for that sector (i.e. EF_Transportation) sheet will displ new names. New factors need to be entered for each of the columns for each new fuel, be sure to u same units listed for each factor. The units cannot be changed; any emission factor must first be con to the correct units before entering them.

Note:
Fuels have a higher heating value (HHV, also called a Gross Caloric Value, GCV) and a lower heating (LHV, also called a Net Caloric Value, NCV). The HHV is the quantity of heat liberated by the cor combustion of a unit volume or weight of a fuel assuming that the produced water vapor is comp

condensed and the heat is recovered. The LHV is a better estimate of usable heat in that most of th contained in water vapor is not recovered and the IPCC recommends using them in emissions calcula However, following the lead of the U.S. EPA, this calculator uses LHVs.

To the top

Biogenic Gases

Following the IPCC protocol, CO_2 emissions from biogenic sources are not included in this inventory. The are several sources of biogenic CO_2, such as landfill gas, incinerator emissions, and biomass combustio Biogenic CO_2 refers to carbon in wood, paper, and grass trimmings that was originally removed from t atmosphere by photosynthesis, and under natural conditions, it would eventually cycle back to t atmosphere as CO_2 due to degradation processes. The quantity of carbon that these natural processes cyc through the earth's atmosphere, waters, soils, and biota is much greater than the quantity added l anthropogenic GHG sources. But the focus of the Framework Convention on Climate Change is anthropogenic emissions - emissions resulting from human activities and subject to human control - becau it is these emissions that have the potential to alter the climate by disrupting the natural balances in carbo biogeochemical cycle, and altering the atmosphere's heat-trapping ability. Thus, for processes with C emissions, if (a) the emissions are from biogenic materials and (b) the materials are grown on a sustainab basis, then those emissions are considered to simply close the loop in the natural carbon cycle -- that is, th return to the atmosphere CO_2 which was originally removed by photosynthesis. In this case, the C emissions from wood and biomass are not counted. On the other hand, CO_2 emissions from burning fos fuels are counted because these emissions would not enter the cycle were it not for human activit Likewise, CH_4 emissions from landfills are counted - even though the source of carbon is primari biogenic, CH_4 would not be emitted were it not for the human activity of landfilling the waste, which creat anaerobic conditions conducive to CH_4 formation. Note that this approach does not distinguish between t timing of CO_2 emissions, provided that they occur in a reasonably short time scale relative to the speed the processes that affect global climate change. In other words, as long as the biogenic carbon wou eventually be released as CO_2, it does not matter whether it is released virtually instantaneously (e.g., fro combustion) or over a period of a few decades (e.g., decomposition on the forest floor).

Notes
Values are taken from the IPCC 3rd assessment report and assume a 100 year period.
Gasoline vehicles are from GREET 1.5a Near-Term Results Table 3.1 "Per-Mile Fuel Consumption and Emissions of Vehicle Operations." Cars and Light Duty Trucks (LDT-1) were selected to represent the commuter fleet. Factors were converted from g/mile to g/gallon using the fuel efficiency. Diesel vehicle emission factors are from heavy duty vehicles (trucks, buses, etc) and are located in the EF Emissions Factors table.
Heating values for liquid fuels were changed from MMBtu/Barrel to MMBtu/gallon using 42gallons/barrel. The heating value for coal is "Commercial Coal." All factors are Higher Heating Values, as used by the US EPA.
Fleet composition (% cars) was derived from total registered vehicles in the US for each year (Table 1-11) and includes passenger cars, light trucks and motorcycles. Average fuel efficiency is from Table 4-11 and includes passenger cars, light trucks and motorcycles.
Airline efficiency (Btu/Passenger Mile) from table 4-20. Factors for Domestic Travel were used, assuming that the vast majority of travel would be within country.
Carbon Content Values are from Table A-15 and A-16.
Factors from table D-2. Factors were converted from g/GJ to kg/MMBtu using the following conversion factors: (g/GJ) x (1 GJ /10^9 J) x (1J / 0.0009486 Btu) x (10^6 Btu / MMBtu) x (1 kg / 1000 g) = (kg/MMBtu). Factors are for "Commercial" operations.
CH4 and N2O emission factors from table E-15. Factors were converted from "g gas / kg fuel" to "kg gas / gallon" using 7.93 barrels jet fuel/metric tonne (from Annex Y - reference 8), 42 gallons/barrel, and 1000 g / kg.
Wood and waste are assumed to have no CO emissions because the carbon in these fuels are considered to be part of the natural carbon cycle. See Intergovernmental Panel on Climate Change, Revised 1996 IPCC Guidelines for National Greenhouse Gas Inventories, Reference Manual (Volume 3), 1996, p. 6.28 (http://www.ipcc-nggip.iges.or.jp/public/gl/invs6a.htm). The CH4 and N2O coefficient for wood is taken from EPA's AP-42 (using their assumed 4500 Btu/lb and their coefficients of 0.1 lb CH /ton and 0.04 lb N O/ton). Coefficients for refuse assumed to be the same as for wood. CH4 and N2O emissions from wood are included becuase they would not have been released during the natural decomposition of the material. Heating value was converted as follows: (4500 Btu/lb) x (2,000 lbs / Short Ton) x (MMBtu / 1,000,000 Btu) = 9.0 MMBtu / Short Ton
Waste Combustion (from Exhibit 6-6): Factors include emissions from combustion of waste but not from biogenic sources following the U.S. EPA guidelines. Factor takes into account Utility CO2 emissions avoided by biogas electric generation. Factor does not include avoided CO2 emissions due to steel recovery and recycling, as few universities will dispose of great amounts of steel. Factors are negative because energy generation from waste results in fewer emissions than would have been emitted by standard utility generation. These factors do not account for other harmful effects of waste combustion. Landfilling (from Exhibit 7-6): Factor includes the emissions associated with transporting the waste to the landfill and CH4 from biogenic sources, but not CO2 resulting from the combustion of biogenic CH4, following the U.S. EPA guidelines. For combustion of landfill gas with electric generation, the factor takes into account Utility CO2 emissions avoided by biogas electric generation. When food discards, yard trimmings, paper, and wood are landfilled, anaerobic bacteria degrade the materials, producing CH4 and CO2. CH4 is counted as an anthropogenic GHG, because even though it is derived from sustainably harvested biogenic sources, degradation would not result in CH4 emissions if not for deposition in landfills. The CO2 is not counted as a GHG in this context because if it were not emitted from landfills, it would be produced through natural decomposition. Because metals do not contain carbon, they do not generate CH4 when landfilled. Plastics do not biodegrade, and therefore do not generate any CH4. Transportation of waste materials to a landfill results in anthropogenic CO2 emissions, due to the combustion of fossil fuels in the vehicles used to haul the wastes. Because food discards, yard trimmings, and paper are not completely decomposed by anaerobic bacteria, some of the carbon in these materials is stored in the landfill. Because this carbon storage would not normally occur under natural conditions (virtually all of the organic material would degrade to CO2, completing the photosynthesis/respiration cycle), this is counted as an anthropogenic sink. Some factors are negative becuase the landfilling process resulted in a net sink of carbon. See source for more details.
Emission factors for cattle (dairy and beef) were derived from national data by dividing total emissions (Table L-11) by total population of animals (Table M-1). This was done to simplify the calculations as much needed data would be hard to estimate at the university scale.
CO2 Emission factors are from year 2000. This was done because data was only available back to 1998 at the subregion scale. Using constant electric emission factors will not capture changing emission due to changes in fuel source. However, it will result in more transparent final emission estimates for the university because all changes in emissions will be due to changes at the university. Factors were converted from lbs/kWh to kg/kWh using 0.453 Kg/lb. Energy efficiency (MMBtu fuel / kWh) is also from year 2000 and was derived by dividing total heat input by total electric output.
Emission factors for CH4 and N2O are averages for 1998-2000. Values are only available by state.
Factors from exhibit 6-6, colum (b). This factor is for on-campus combustion of waste. Thus factor does not include avoided emissions because combustion is on campus and no emissions are being avoided. Factor assumes no transportation emissions and no avoided emissions due to steel recovery.
Efficiencies are assumed to be the same for chilled water and steam production.
Production efficiencies from Table 2.
Factor is for composted "yard trimmings." Factor estimates CO2 sink from increased humus formation and soil carbon restoration. Factor includes CO2 emissions from transportation.
Aggregated fraction of N in other commercial organic fertilizers = 4.1%
Choose from various units using this widely accepted tool.
