# **Counting the cost of Carbon**

Lesson 5a: Student worksheet

## Introduction

Scientists are able to detect and analyse the carbon dioxide concentrations in many different spheres of the carbon cycle, including the atmosphere and the hydrosphere in particular.

They can do this through a variety of methods, including taking regular samples of the air at particular places over long periods of time, and taking samples of ice (called ice cores) from places like Antarctica, and analysing these for changes in the concentration of dissolved carbon dioxide in the frozen water.

Carbon dioxide concentrations are usually measured in **parts per million**, or **ppm**. Climate scientists do this by calculating the total number of air or water particles in a particular sample and then working out how many of these are carbon dioxide molecules. They then convert this number into the number of carbon dioxide molecules per million molecules of air or water.

Most climate scientists agree that if the average number of parts per million of carbon dioxide in the Earth's atmosphere reaches 350 ppm, then the impacts of climate change will be significant. Unfortunately, at this point, the Earth's atmosphere is currently registering 395.10 ppm according to the web site, Pro Oxygen (2013), where you can also check out the most up-to-date figure.

That's the bad news. But the good news is that the Earth's carbon dioxide concentration is not fixed. It can both increase and decrease depending on the actions that are taken by individuals, communities, countries and all global citizens. You, your family, your school and your local community can take positive action to decrease the amount of carbon dioxide present in our atmosphere.

In this activity, you will be observing and analysing a number of sets of data, collected over time by climate scientists, and showing some interesting changes in carbon dioxide concentrations.

## Activity 1: Recent carbon dioxide concentrations

When referring to carbon dioxide concentrations, the term, *recent*, really means *since records began*. Recent refers to any data that humans have recorded for themselves at a particular place at regular intervals.

The following data set showing carbon dioxide concentrations from 1750 to 1990 is an example of recent data.

Year	Carbon dioxide concentration
1750	282 ppm
1800	283 ppm
1850	290 ppm
1900	297 ppm
1950	312 ppm
1980	335 ppm
1990	350 ppm

Complete the graph below to show the data from the table above. Label the horizontal axis 'Year' and the vertical axis 'Carbon dioxide concentration'. Give the graph an appropriate title.

In fact, the annual carbon dioxide concentration for the year 2000, recorded at 369.52 ppm, can be found at Earth System Research Laboratory – Global Monitoring Division (2013).

## Activity 2: Carbon dioxide concentrations at Mauna Loa, Hawaii

In March 1958, at a scientific laboratory in Mauna Loa, Hawaii, a scientist named C. David Keeling first began to record direct measurements of carbon dioxide concentration in the atmosphere. This laboratory, a facility of the National Oceanic and Atmospheric Administration, has recorded this same data ever since.

You can see the now famous summary of this data in the graph below. The red line shows the actual data and the black line shows the seasonally corrected data.

Graph: Atmospheric CO2 at Mauna Loa Observatory, Hawaii

#### Sources

ESRL Global Monitoring Division 2013, Atmospheric CO<sub>2</sub> at Mauna Loa Observatory, viewed 29 December 2013, <a href="http://www.esrl.noaa.gov/gmd/ccgg/trends/index.html">http://www.esrl.noaa.gov/gmd/ccgg/trends/index.html</a>. You will notice that the red line moves up and down in a regular pattern. Mauna Loa, Hawaii measures the atmospheric carbon dioxide concentration of the northern hemisphere. In the northern hemisphere, most trees are deciduous. That is, they lose their leaves every autumn and grow new ones every spring.

<b>Q1a</b> : When a tree loses its leaves, they drop to the ground where they decompo leaves moves into the soil. Where does the remaining carbon in the leaves	ose. Some of the carbon in the go?
<b>21b</b> . If most of the trees in the northern hemisphere lost their leaves at approxi	mately the same time, how
might this affect the measurement of atmospheric carbon dioxide concen	Itrations at Mauna Loa?
boroforo what climate scientists have done is take an <b>average</b> of the carbon di	
oa each year. This means that any increases in CO <sub>2</sub> due to leaf fall, and decrease	in $CO_2$ due to leaf regrowth
re taken into account.

## Activity 3: Carbon dioxide concentrations over geologic time

When scientists talk about geologic time, they are referring to the distant past. Geologic time refers to time stretching back to when the Earth first formed and all the time between then and now. It is called 'geologic' because the information about such distant times can only be found in samples of the Earth. Scientists who study the Earth are called geologists and the study of the Earth is called geology. The time that humans have lived on Earth is a very tiny fraction of geologic time.

If climate scientists want to look at how carbon dioxide concentrations have changed over geologic time, they cannot rely on data collected by humans themselves. They need to look at rocks and ice. Scientists are able to look at 'fossilised' air trapped in ice cores taken from deep down in Antarctic ice. This 'fossilised' air takes the form of tiny air bubbles that have been trapped in the ice ever since the ice was formed. Therefore, the deeper you go down into the ice, the earlier in geologic time the bubbles were trapped.

Amazingly, information from ice has been dated up to 850,000 years ago!

#### In a nutshell – About how ice cores are made

# Calculate your own carbon

Lesson 5b: Student worksheet

## Introduction

### What is an ecological footprint?

An ecological footprint, or ecofootprint, is one way of measuring how much carbon dioxide your actions and activities release into the atmosphere. This is shown in terms of the amount of land you need to produce all the energy and resources you need for everything that you do.

The infographic below summarises this for you.

### What is an ecological footprint

It is a measure of how much biologically productive land and water an individual, population or activity requires to produce all the resources it consumes, and to absorb the waste it generate. The Ecological Footprint is usually measured in global hectares (gha).

### How can I calculate my ecofootprint?

The simplest way to calculate your ecofootprint is to use a specially designed online calculator. All you need to do is answer some questions about what products (e.g. a car, a clothes dryer) you use and how often you use them, as well as what types of energy you use (e.g. home gas and electricity use) and how much you use.

As well as looking at all the energy and resources you use, the ecofootprint calculator will take into account the environmentally friendly choices you make. For example, whether or not you use public transport rather than a car, whether your house has solar panels on it, etc.

A simple way of summarising what a ecofootprint calculator may includes for different technology devices and the internet is shown below.

#### What does my ecofootprint tell me?

Once you have used the online calculator to input all of the necessary information, the calculator will convert this information into an equivalent **amount of land** needed to supply you with everything you need to live your current lifestyle.

This amount of land is given in global hectares.

Your ecofootprint can also be converted into the **number of Earths** that you would need if ALL the individuals on the planet lived like you. The graphic below explains this idea.

 Image: NY ECOLOGICAL FOOTPRINT
 If everyone on the planet lived my lifestyle, we would need:

#### How can I use my ecofootprint?

You can use your ecofootprint in two main ways.

1. To develop a personal plan for a more sustainable lifestyle.

You can analyse the different parts of your ecological footprint and identify the areas where you could take positive action to reduce it. You can then brainstorm some ways that you could reduce the number of global hectares you require to sustain your lifestyle. Once you have the strategies in mind, you will need to make a plan for how to put them into action. It is always a good idea to check how you are going regularly and update your plan if you need to.

2. To compare your footprint to the footprints of other people around the world.

You can also compare your own ecofootprint with that of other people (such as classmates), or even compare your ecofootprint with the average ecofootprint of a person in a particular region (such as the state of Victoria), a particular country (such as Australia or Timor Leste), or the average global citizen.

In the diagram below, you can see the average number of Earths that people in 5 different countries/continents require to sustain their particular lifestyle (but not an equal lifestyle).

The drawing below shows how many planets are necessary to sustain the lifestyle of the different continents

## Calculate your ecofootprint

EPA Victoria's personal Ecological Footprint calculator (EPA Victoria 2013) is a good one to use, as it is specifically for Australians. You can find it here: <a href="http://www.epa.vic.gov.au/ecologicalfootprint/globalfootprint/index.asp">http://www.epa.vic.gov.au/ecologicalfootprint/globalfootprint/globalfootprint/index.asp</a>

Try completing the calculator using the 'basic' information version first. Once you have completed it and answered the questions below, you may like to have a go at the 'detailed' version.

#### What is your personal ecofootprint?

In global hectares:	
In Earths:	

#### Analyse your ecofootprint

**Q1**: What are the **three** main areas (e.g. consumption of meat) of your lifestyle that contribute most to your ecological footprint?

Area 1:	 	 	 	
Area 2:				
Area 3:				

Q2: Choose one of the three areas listed in Q1 above to complete the following table.

Area of choice:	
What specific action will I take to actively reduce my ecofootprint in this area?	I will
<b>When</b> will I start to make this change?	I will start

Area of choice: (contir	ned from previous page)
<b>How</b> often does this action occur? (e.g. daily, weekly, etc.)	I will do this every
<b>How</b> regularly will I check that this change is occurring?	I will monitor this every
How will I know that I have succeeded in making this change?	I know I have succeeded when
What specific action will I take if, at first, I am not able to successfully make this change?	I will

#### Q3a: The table below shows the average ecological footprints for a number of different populations.

Table: The ecological footprints per capita of various countries and regions

Geographical location	Average number of global hectares required to sustain a person in their current lifestyle
Victoria	6.81
Australia	7.81
Timor Leste	0.4 <sup>2</sup>
South-east Asia (excluding Australia)	<0.83
U.S.A.	8.00 <sup>2</sup>
United Arab Emirates	10.7 <sup>2</sup>
U.K.	4.9 <sup>2</sup>
New Zealand	4.9 <sup>2</sup>
The world	2.71
