#### **Chapter 10: Circular Motion**

**Centripetal Force** 

# 35

## **The Flying Pig**

#### **Purpose**

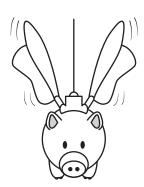

To show that the net force for a conical pendulum is  $mv^2/r$ 

#### **Required Equipment/Supplies**

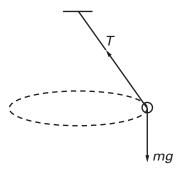

flying pig apparatus (or equivalent) available from Arbor Scientific vertical and horizontal rod table clamp stopwatch meterstick

#### **Discussion**

When an object travels at constant speed along a circular path, we say it has uniform circular motion (if its speed were changing, then its motion would not be uniform). Any object moving in uniform circular motion is accelerated toward the center of its circular path. This acceleration is called *centripetal acceleration*, and equals  $v^2/r$ , where v is the speed of the object and r is the radius of the circular path. Although the net force on any object equals ma, during uniform circular motion, the net force, called *centripetal force*, equals  $mv^2/r$  and is directed *toward the center*. When an object suspended by a string moves in a circular path the centripetal force creates a *conical pendulum*. The string of a conical pendulum sweeps out a right-circular cone. In this experiment you will measure the speed of an object that produces a conical pendulum and show that the net force is  $mv^2/r$ .

- 1. Draw the force vectors (a free-body diagram) that act on a conical pendulum. Ignoring air resistance, note that only two forces act on the pendulum bob—in this case, the pig. One is *mg*, the force due to gravity, and the other is string tension, *T*.
- **2.** Resolve the tension into horizontal and vertical components. Represent the tension T with a solid line and its components with dashed lines. Also label the angle between the tension T and the vertical as  $\theta$ .

**3.** Does the pig accelerate in the *vertical* direction? What does this tell you about the magnitude of the vertical component of *T* and *mg*?

 $T_{y=}$ 

**4.** Does the pig accelerate in the horizontal (radial) direction? Knowing that the net force in the radial direction for any object in uniform circular motion is the centripetal force, what does this tell you about the magnitude of the horizontal component of T and  $mv^2/r$ ?

 $T_{y} =$ 

**5.** Write an equation that shows how the horizontal and vertical components of T are related to the weight and the centripetal force.

*Hint*:  $\tan \theta = \frac{\text{opposite}}{\text{adjacent}} = \frac{T_x}{T_y} =$ 

**6.** Algebraically solve for the tangential speed of the pendulum from your equation in Question 5. Show your work.

*υ* = \_\_\_\_\_

## **Procedure**

Set up the flying pig. (Note: Anything that "flies" in a circle works here—whether it be toy airplane, a toy flying pig or flying cow, etc.) Be careful not to damage their delicate wings as you click them into their fixed-wing position. Ask your instructor to check your pivot *before* switching on battery power. Carefully hold the pig by its body and give it a *slight* shove about 30° from the vertical, just enough so that the pig "flies" in a circle. The goal is to launch the pig *tangent* to the circle of flight. It's better to launch it too easy than too hard. If the pig does not fly in a stable circle in 10 seconds or so, carefully grab it and try launching it again.

**Step 1:** Once the pig is up and flying in a circle of constant radius, measure the radius of the circle as accurately as you can. Express your answer in meters.

*r* = \_\_\_\_\_

**Step 2:** There are several ways to determine the angle the string makes with the vertical,  $\theta$ . Using a protractor may not be as practical as other methods you may devise. Describe your method and then record your value for  $\theta$ . Include a sketch.

Method: \_\_\_\_\_

 $\theta$  = \_\_\_\_\_

**Step 3:** Using the values for r and  $\theta$  you determined in Steps 7 and 8, compute the theoretical speed of the pig using the formula you derived for the speed in Steps 5 and 6. (Remember, this speed is based on  $F_{\rm net} = mv^2/r$ .)

*ν* = \_\_\_\_\_

**Step 4:** In Step 9 you calculated the *theoretical* speed of the pig. Now, actually *measure* the speed of the pig and see how these two values for the speed compare. Since the pig flies in a circle, the speed is the circumference  $(2\pi r)$  divided by the time t for one complete revolution. To make your measurements of t more precise, measure the time it takes the pig to make 10 revolutions—then divide by 10.

10*t* = \_\_\_\_\_ s (for ten revolutions)

So for one revolution, t =\_\_\_\_\_s.

**Step 5:** Using your measurement of *r*, compute the speed of the pig:

$$v = d/t = 2\pi r/t =$$
 \_\_\_\_\_ m/s

**Step 6:** Compute the percent difference between the value for the speed you computed in Step 9 and measured in Step 11. (Use the calculated speed as the known.)

% difference = \_\_\_\_\_

### **Analysis**

- **7.** What techniques for measuring r and  $\theta$  would you recommend for best results?
- **8.** What do you conclude about the magnitude of the string tension compared with the weight of the pig? Choose one: For uniform circular motion, the tension will always be (less than) (the same as) (greater than) the weight.
- **9.** What do you conclude about the direction of the net force that keeps the flying pig in uniform circular motion?

10.	Choose one: For uniform circular motion, the centripetal force will always be (less than) (the same as) (greater than) the tension in the string.
11.	How does the pig overcome air friction?
12.	List sources of error.
