

Medical Marijuana Test Report

sample **CA457**

Client: **Cheebe Chews**

Item: **Quad Dose - Sativa**

Sample Date: 5/3/11

Testing Date: 5/6/11

Client Batch ID: N/A

Item Notes: Item weight 9.794.

TEST RESULTS

sample CA457

Per Unit: 10 grams

THC: 80.8 mg

CBD: 2.6 mg

THC	THC-A(1)	Total THC	CBD	CBD-A(1)	Total CBD	CBN	Moisture Content	% THC-A Converted to THC(2)
80.8	1.1	81.9	2.6	0.8	3.4	1.5	N/A	98.6%
		94.4%			3.9%	1.7%	Cannabinoid Mix(3)	
8.08	0.11	8.19	0.26	0.08	0.34	0.15	mg per gram of sample	

(1) THC-A and CBD-A are the "inactive", acidic forms of the THC and CBD molecules, which convert to THC and CBD given time and/or heat. THC-A and CBD-A counts are adjusted to account for the greater weight of the acidic molecules.

(2) This shows the amount of initial THC-A converted to THC by the time of testing. At harvest, this number is near zero. For well-cured plant material, this figure generally ranges from 5% to 20%. For edibles and tinctures, this number is generally over 85%.

(3) This shows the relative levels of the measured cannabinoids in the sample. For example, some patients report "CBD-type" effects when CBD comprises more than around 10% of the cannabinoid mix.

The Biochemistry of Marijuana

The major active components of marijuana are a family of chemical compounds known as cannabinoids. There are over 60 different identified cannabinoids, though only a handful have been closely studied; as a family, they have remarkable medical properties. Researchers have found cannabinoids to have widely varied effects, from psychoactivity to pain and nausea relief to anti-inflammatory, cancer inhibiting and antibacterial activity.

Cannabinoids are effective because they mimic natural neurotransmitters – the chemical messengers between cells – that act in the human brain and throughout the body. The different cannabinoids, when ingested or inhaled, interact with the body in complex ways. Some compounds enhance or inhibit the effects of others, or help alleviate the side effects that one compound alone might cause. The mix of different cannabinoids in a particular sample of marijuana are largely governed by the plant's genetics and maturity at harvest, while the total levels of cannabinoids are dictated both by genetics and the overall quality of the growing conditions.

THC, or delta-9 tetrahydrocannabinol, is the primary psychoactive component of marijuana. It is responsible for the high of marijuana, and is likely the direct or indirect cause of unwanted side effects such as anxiety, detachment and paranoia. When marijuana is harvested, THC is primarily present in its "inactive", acidic form, known as THC-A or THC-COOH, which has little psychoactive effect. As marijuana cures, the THC-A partially converts to THC; the conversion is accelerated as marijuana is heated during cooking or smoking.

CBD, or cannabidiol, is the second most prominent and studied cannabinoid, and is the major cannabinoid in “hemp-type” marijuana. CBD has many effects in itself, and also appears to alleviate many of the side effects of THC, including sleepiness and loss of memory.

CBN, or cannabinol, is the breakdown product of THC; high levels indicate that the marijuana may be relatively old or has been stored at high temperatures.

Research has demonstrated these properties, among others, of the different cannabinoids:

THC	CBD	CBN	Other Cannabinoids*
Psychoactivity Relieves pain Induces sleep Reduces inflammation Anti-oxidant Reduces nausea Reduces intraocular pressure in glaucoma Protects nervous system	Relieves anxiety Relieves pain Reduces inflammation Anti-oxidant Antipsychotic Reduces heart rate Reduces blood pressure Reduces muscle spasms Reduces THC side effects	Induces sleep Antibacterial	Psychoactivity Reduce Inflammation Relieve pain Antibacterial Antifungal

* Includes cannabichromene (CBC), cannabigerol (CBG) and tetrahydrocannabivarin (THCV), which are generally found at levels below 2% by weight. We do not currently measure these cannabinoids.

Other medicinal components of marijuana: In addition to the cannabinoids, there are a number of other compounds in marijuana that are believed to have psychoactive or medicinal properties. These include many of the 100 or more terpene compounds that give marijuana its characteristic smell. Little is known about most of these compounds, although some are found in other plants and thus have been more extensively studied. Beta-myrcene, for example, is a terpene with potent pain relief and anti-inflammatory effects. We do not currently measure these other components.

Rm3's Testing Methods

At Rm3 Labs we use a testing methodology known as High-Performance Thin Layer Chromatography, or HPTLC. This method is widely used in the herbal, nutritional supplement and pharmaceutical industries to ensure the purity and strength of products. For each test, the client provides us a small sample of the product. We extract the cannabinoids from the sample, and then separate the individual components. Analysis of the separated components is done by computer.

In analyzing samples, we screen out seeds and large stems, as including them in the sample may produce large variations in results. Cannabinoids are measured as a percentage of dry weight, to eliminate the effect of particularly moist storage conditions on the sample. End users should inspect the product they receive for excessive seeds, stems or moisture levels.

The Limitations of our Test Methods

We do not test an entire “batch” of product; we only test the sample provided by the client. When testing marijuana, we ask for as representative a sample as possible; however, it is possible that the product received by a patient may be materially different from the sample we've tested.

There are currently no established protocols for medical marijuana testing in the U.S. As a result, each lab uses its own procedures, and results from different labs may not be directly comparable.

Results of our tests, and this report, may be used or displayed only by the client and only in connection with the batch of product from which the test sample was taken. By submitting a sample for analysis, the client has represented that product from which the sample has been taken is being held by the client in full compliance with Colorado state and local medical marijuana laws, and such product or any product made therefrom will only be offered for sale in compliance with such laws.
