Received: 10 August 2010, Accepted: 27 September 2010

**Abstract:** The vibrational frequencies and  $^1\text{H}$  and  $^{13}\text{C}$  chemical shifts of choline halides have been calculated using density functional theory (B3LYP) method with 6-311++G(d, p) and 6-31 G(d, p) basis set level in Gaussian 03 and Parallel Quantum Solutions (PQS) ab initio packages programs, respectively. The calculated optimized geometric parameters, vibrational frequencies and chemical shifts were seen to be a very good agreement with the experimental data. The electronegativity influence of the halogen substitutions on the vibrational frequencies and chemical shifts have also been investigated. It was observed that the chemical shifts for H nucleus, especially the most near nucleus to the halogen atom decrease while it increases for C nucleus. The roughly linear variation of the chemical shift with the electronegativity of the halogen, whatever the shielding for C nucleus or deshielding for H nucleus is, has been commented that the local electron density near the halogen atom is affected.

**Key words:** Choline halides, vibrational spectroscopy, chemical shift, B3LYP, Gaussian, PQS

## Kolin Halidlerin (F, Cl, Br) Kimyasal Kaymalarının ve Titreşim Frekanslarının Teorik Çalışması

**Özet:** Taban setleri 6-311++G(d,p) ve 6-31G(d,p) olan yoğunluk fonksiyon kuramı (B3LYP) yöntemi kullanılarak kolin halojenlerinin (F, Cl, Br), Gaussian 03 programında titreşim frekansları ve Paralel Quantum Solutions (PQS) programında ise,  $^1\text{H}$  ve  $^{13}\text{C}$  çekirdeklerinin kimyasal kaymaları hesaplandı. Hesaplanan optimize geometrik yapı parametreleri, titreşim frekansları ve kimyasal kaymalar, deneyel verilerle çok iyi uyuymaktadır. Kimyasal kaymala ve titreşim frekanslarına, halojen katkılamalarının, yani elektronegatifliğin etkileri incelendi. Kimyasal kaymaların, H çekirdeği için özellikle halojen atomuna en yakın çekirdekler olmak üzere azalırken, C çekirdeği için aynı sıralamaya arttığını gözledik. Halojenin elektronegatifliği ile kimyasal kaymanın kabaca çizgisel değişimi, C çekirdeği için ekranlanma ya da H çekirdeği için ekranlanmama ne olursa olsun, halojen atomu yakınındaki yerel elektron yoğunluğunun değişimin olarak yorumlandı.

**Anahtar kelimeler:** Kolin halidleri, titreşim spektroskopisi; kimyasal kayma; B3LYP, Gaussian, PQS

### 1. Introduction

Choline compounds are interest because of both the unusual radiation sensitivity and the frequent occurrence in biological systems. They are components of complex lipids, and can act as transmethylation agents [1]. Köksal and Bahçeli, have studied the effect of methyl group reorientation and spin diffusion on spin-lattice relaxation in some choline and acetylcholine halides by NMR spectroscopy [2]. Likewise, Akin and Harmon have

investigated the effects of anesthetics on hydration of choline and acetylcholine halides in aqueous solution using NMR spectroscopy [3]. Harmon and et al. have studied the high-temperature phases of choline bromide and choline iodide by IR spectroscopy [4]. NMR and IR studies of the lower hydrates of choline and acetylcholine halides have been done by some authors [5-7]. The crystal structure of choline chloride was investigated using X-ray diffraction method [8,9].

In the present study we wish to report the vibrational analysis and optimized molecular geometries and chemical shifts of choline halides having a central importance for the study of the pharmacologically active molecules, by means of density functional theory (B3LYP) method in Gaussian and PQS package programs, respectively.

## **2. Material and Method**

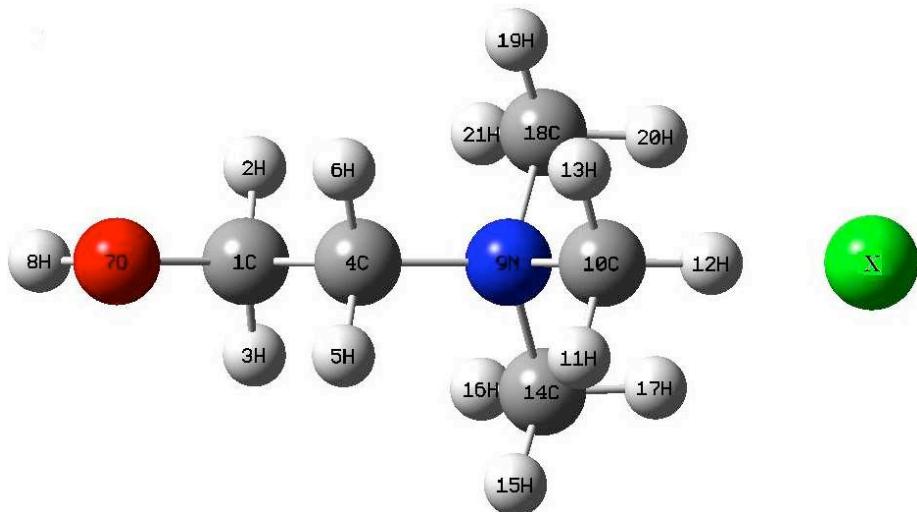

### *2.1. Computational methods*

The optimized structure parameters and vibrational frequencies for choline halides ( $\text{ChF}$ ,  $\text{ChCl}$ ,  $\text{ChBr}$ ) have been calculated by B3LYP methods at 6-311++G(d,p) basis set level in Gaussian [10]. The vibrational modes were assigned on the basis of visual inspection of each of the vibrational modes by Gauss-View molecular visualization program [11]. The calculated vibrations were multiplied with a scale factor of 0.9614 [12]. By using PQS ab initio package program [13],  $^1\text{H}$  and  $^{13}\text{C}$  NMR chemical shifts of all the compounds have been calculated within GIAO approach applying B3LYP method with 6-31 G(d,p) basis set. Since the NMR spectra of the compounds studied in this work are taken in aqueous solutions we have carried out the calculations in solutions by using the conductor-like screening model (COSMO) [14,15] as implemented in PQS by using water as solvent. These calculations produce absolute shielding values that are converted into chemical shifts by subtraction from the shielding value for TMS ( $^{13}\text{C}$  and  $^1\text{H}$  chemical shifts are 192.6365 ppm and 31.7099 ppm; respectively).

## **3. Results and Discussion**

### *3.1. Ground State Conformations*

After having a few different conformation calculations we have decided the ground state conformations of the choline halides which have minimum energy and do not cause imaginary frequencies. These conformations can be seen in Fig. 1. The sum of electronic and zero-point energies of the ground state conformations of the compounds are -428.66 hartree/par for  $\text{ChF}$ , -789.04 hartree/par for  $\text{ChCl}$  and -2902.96 hartree/par for  $\text{ChBr}$ , respectively.

**Figure 1.** Optimized molecular structures of choline halides ( $X = F, Cl, Br$ ).

### 3.2. Vibrational symmetries

As seen from Fig. 1 the choline halides belong to the point group  $C_s$ . For an N-atomic molecule the three Cartesian displacements of the N-atoms provide  $3N$  internal modes, namely;

$$\Gamma_{\text{inter.}} = 3N.$$

From the following character table for the  $C_s$  point group,

$C_s$	E	$\sigma_h$	
$A'$	1	1	$x, y, R_z; x^2, y^2, z^2, xy$
$A''$	1	-1	$z, R_x, R_y; yz, xz$
$\chi$	66	14	

since  $\Gamma_{\text{trans.}} = 2A' + A''$  and  $\Gamma_{\text{rot.}} = A' + 2A''$ , we obtain

$$\Gamma_{\text{vib.}} = \Gamma_{\text{inter.}} - \Gamma_{\text{trans.}} - \Gamma_{\text{rot.}} = \Gamma_{\text{inter.}} - 3A' - 3A''$$

normal modes of vibration. All the vibrations are active both infrared (IR) and Raman (R). Since the molecules are in the  $C_s$  group, the vibrations being anti-symmetric through the mirror plane  $\sigma_h$  will belong to the species  $A''$  and the ones being symmetric through  $\sigma_h$  to the species  $A'$ . So, the numbers of vibration modes for all the choline halides are as follows:

$$\Gamma_{\text{vib.}} = 34A' + 26A'' .$$

This was corrected by the inspection of each of the vibrational mode on Gauss-View molecular visual program.

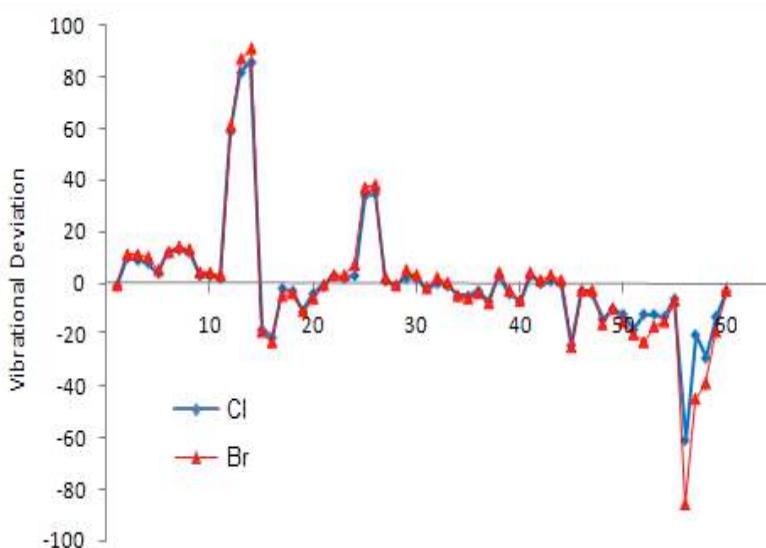

### 3.3. Molecular geometries

The calculated optimized structure parameters of all the title compounds are summarized in Table 1. The experimental data [8,9] for ChCl are also given in the table. Taking into account that the molecular geometry in the vapour phase may be different from the one in the solid phase, owing to extended hydrogen bonding and stacking interactions there is reasonable agreement between the calculated and experimental geometric parameters. The differences are also attributed to that the experimental data taken X-ray crystallographic analysis have been obtained the averaged geometries of the structures of ChCl. The correlation values between experimental and calculated parameters can be seen in the last line of the table.

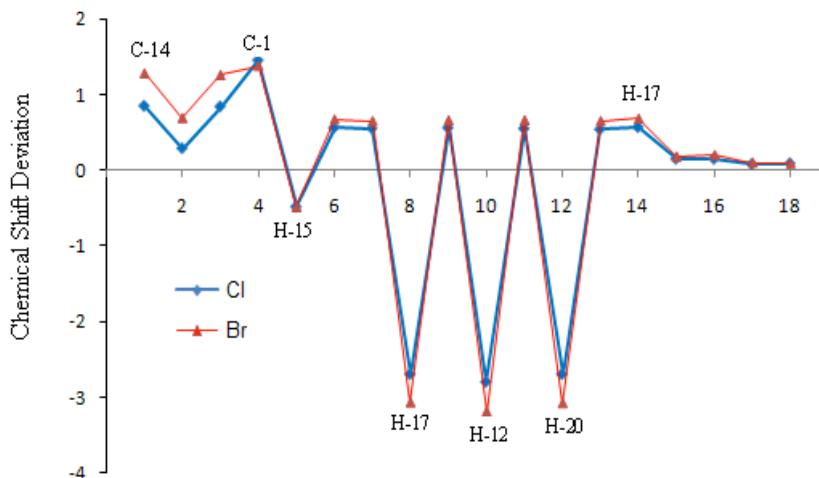

### 3.4. Vibrational frequencies

The resulting vibrational frequencies for the optimized geometries of the choline halides are given in Table 2. For comparison the table also show the experimental vibrational frequencies for ChCl [16,17]. From the table we can see that the largest variation between the calculated and experimental frequencies is for the OH stretching vibration. This may partially be attributed to the anharmonicity of the OH group. The proposed vibrational assignments are given in the second column of Table 2. They are made by the inspection of each of the vibrational mode by Gauss-View molecular visualization program. The symmetry species of all the vibrations are written in the first column of the table.

As seen from Table 2 the calculated frequencies in the higher frequency region increase while the electronegativity of the halide decrease in the order F < Cl < Br. From the table this can clearly be seen for especially the CH<sub>2</sub> and CH<sub>3</sub> groups. But, for the lattice vibrations in the lower frequency region this situation is vice versa. In Fig. 2 are drawn the deviations of the calculated frequencies of ChCl and ChBr relative to ChF. Mean vibrational deviation is 12.21 for ChCl and 14.75 for ChBr.

**Figure 2.** Calculated vibrational deviations of ChCl and ChBr relative to ChF.

**Figure 3.** Calculated chemical shift deviations of ChCl and ChBr relative to ChF.

### 3.5. Chemical shifts

An important factor influencing on chemical shift is electron density expected to be altered by the substitution of a halogen. Table 3 and Table 4 indicate the  $^1\text{H}$  and  $^{13}\text{C}$  chemical shifts of the choline halides given as group and atomic, respectively. They were calculated within GIAO approach applying B3LYP method with 6-31G(d,p) basis set by using PQS ab initio package program which gives generally better agreement with experimental results for chemical shifts calculations than Gaussian. The experimental chemical shifts for ChCl in the table are taken from the references [18,19]. The chemical shifts given as group in Table 3 are the mean values of the chemical shifts of the single atoms in any group. As seen the experimental and calculated values are very close to each other. The correlation values between experimental and calculated chemical shifts for ChCl can be seen in the last line of the table.

In Fig.3 are drawn the deviations of the atomic chemical shifts of ChCl and ChBr relative to ChF. From Fig. 3 and Table 4 we see the  $^1\text{H}$  chemical shifts are in the order  $\delta(\text{F}) > \delta(\text{Cl}) > \delta(\text{Br})$  while those of  $^{13}\text{C}$  have the opposite order ( $\delta(\text{Br}) > \delta(\text{Cl}) > \delta(\text{F})$ ). As expected the effect of the halogen substitution on the chemical shifts of the nearest H nucleus (H-17, H-12 and H-20) are highest (see Fig. 1). The variation of the chemical shift with the electronegativity of the halogen, whether shielding for C nucleus or deshielding for H nucleus, indicates that the local electron density is affected due to the halogen substitution at the X position. As shown in Fig.3, the  $^{13}\text{C}$  chemical shifts are also correlated with the electronegativity of the substituent at the position X. The highly electronegative fluoride substituent leads to a strong electron-density-withdrawing effect on the resonance of  $^{13}\text{C}$ . Therefore the ordering of the halogen-substitution effect for C nucleus is  $\delta(\text{Br}) > \delta(\text{Cl}) > \delta(\text{F})$  which is vice versa for H nucleus.

**Table 4.** Calculated  $^1\text{H}$  and  $^{13}\text{C}$  NMR chemical shifts of choline halides given as atomic.

Atom	Calculated chemical shifts (ppm) B3LYP 6-31G(d,p)		
	ChF	ChCl	ChBr
C-14	49.24	50.09	50.52
C-10	55.42	55.71	56.11
C-18	49.36	50.20	50.62
C-4	66.62	68.07	68.00
C-1	56.98	56.50	56.49
H-15	2.03	2.59	2.70
H-16	2.22	2.77	2.87
H-17	6.99	4.30	3.92
H-11	2.17	2.73	2.83
H-12	7.22	4.43	4.03
H-13	2.16	2.71	2.82
H-20	6.96	4.27	3.88
H-21	2.19	2.73	2.84
H-19	1.97	2.54	2.65
H-5	2.95	3.10	3.13
H-6	2.78	2.93	2.98
H-2	4.08	4.16	4.18
H-3	3.92	4.01	4.01

#### 4. Summary and Conclusion

The optimized structure parameters, vibrational frequencies and chemical shifts of choline halides were theoretically examined using ab initio B3LYP methods at 6-311++G(d,p) and 6-31G(d,p) basis set levels in Gaussian and PQS package programs. The comparison of the experimental and calculated results showed a well agreement with each other. The electronegativity influence of the halogen substitution on the vibrational frequencies and chemical shifts have also been investigated. It was seen that the calculated frequencies generally increase in the order F < Cl < Br while the chemical shifts decreases in the same trend for H nucleus although the situation is vice versa for C nucleus. These were attributed the variation of the force constants, the molecular weight and the local electron density on the H and C nucleus which is affected due to the halogen substitution at the X position.
