

- electrolytes: substances that dissolve in water to form charge-carrying solutions

* Electrolytes form ions in solution - (ions that are mobile are able to carry charge!). These IONS can undergo certain kinds of chemistry!

IONIC THEORY

- the idea that certain compounds DISSOCIATE in water to form free IONS

What kind of compounds?

- Soluble ionic compounds
- Acids (strong AND weak)
- Bases (strong AND weak)

The ions formed may interact with each other to form NEW compounds!

Strong vs weak?

- If an electrolyte COMPLETELY IONIZES in water, it's said to be STRONG
- If an electrolyte only PARTIALLY IONIZES in water, it's said to be WEAK
- Both kinds of electrolyte undergo similar kinds of chemistry.

Ionic theory experiment

Simple conductivity tester: The stronger the electrolyte, the brighter the light.

SOME PURE COMPOUNDS (MOLECULAR AND IONIC)

DISTILLED WATER No light. Pure water is a **NONCONDUCTOR**.

SOLID SODIUM CHLORIDE

Contains ions, but since they're locked in a crystal structure and unable to move, no light.

SOLID SUCROSE $C_{12}H_{22}O_{11}$

No light. Like water, sucrose is a molecular substance. No charge carriers.

MOLECULAR AND IONIC SOLUTIONS**SODIUM CHLORIDE + WATER**

Bright light. Sodium chloride is an **ELECTROLYTE** (probably a **STRONG ELECTROLYTE** based on the brightness). It breaks apart in water to form free sodium and chloride ions

SUCROSE + WATER

No light. The sugar water is a nonconducting solution. Sugar is a **NONELECTROLYTE** - it does not break apart in water to form ions.

ACIDS**PURE (GLACIAL) ACETIC ACID**

No light. Pure acetic acid is a **NONCONDUCTOR**, meaning that there are no ions present in the liquid state.

ACETIC ACID + WATER

Bulb lights, but a little dim. Still, acetic acid is an **ELECTROLYTE** (probably a **WEAK ELECTROLYTE**). Acetic acid must react with water to make ions.

2M ACETIC ACID (AQUEOUS)

Light bulb lights, but not as brightly as 2M HCl. **WEAK ELECTROLYTE**.

2M HYDROCHLORIC ACID (AQUEOUS)

Light bulb lights brightly. **STRONG ELECTROLYTE**. (Or at least, stronger than acetic acid!) For reference, HCl is considered a strong electrolyte like NaCl.

- provides an easy-to-understand MECHANISM for certain kinds of chemical reactions.
 - "Exchange" reactions. (a.k.a "double replacement" reactions)

These free ions mix and can interact with each other!

"ion soup"!

Insoluble AgCl falls out of solution as it is formed - "precipitation"

Looking a bit more closely...

The nitrate and sodium ions do not really participate in this reaction. They start and end in exactly the same state. We call them "SPECTATOR IONS".

(The net ionic equation shows only ions and substances that change during the course of the reaction!)

- The net ionic equation tells us that any source of aqueous silver and chloride ions will exhibit this same chemistry, not just silver nitrate and sodium chloride!

115 A bit more about molecular, ionic, and net ionic equations

- molecular equations: Represent all substances (even ionic substances) as if they were molecules. Include spectator ions, and do not show charges on ions. Traditional chemical equations.

- ionic equations: Show all free ions - including spectators - in a chemical reaction. Molecules and WEAK electrolytes are shown as molecules. STRONG electrolytes (like HCl) are shown as ions. Ions that are part of undissolved ionic compounds are shown as molecules.

- NET ionic equation: An ionic equation that leaves out spectator ions. Intended to show only things that actually change in a reaction.

* You can get from the complete ionic equation to the net ionic equation by crossing out the spectator ions on both sides.

116 "Undissolved ionic compounds":

How can I tell if an ionic compound dissolves in water?

- consult experimental data: "solubility rules"!

A few of the "rules"...

- Compounds that contain a Group IA cation (or ammonium) are soluble
- Nitrates and acetates are soluble
- Carbonates, phosphates, and hydroxides tend to be insoluble

See p 129 9th edition

... or see the web site for a solubility chart.

AgCl : (#3) AgCl is insoluble.

$\text{Mg}(\text{NO}_3)_2$: (#2) dissolves in water (soluble)

$\text{Fe}(\text{OH})_3$: (#8) insoluble .

Exchange Chemistry

- Three kinds of exchange chemistry.

① PRECIPITATION

② ACID/BASE or NEUTRALIZATION

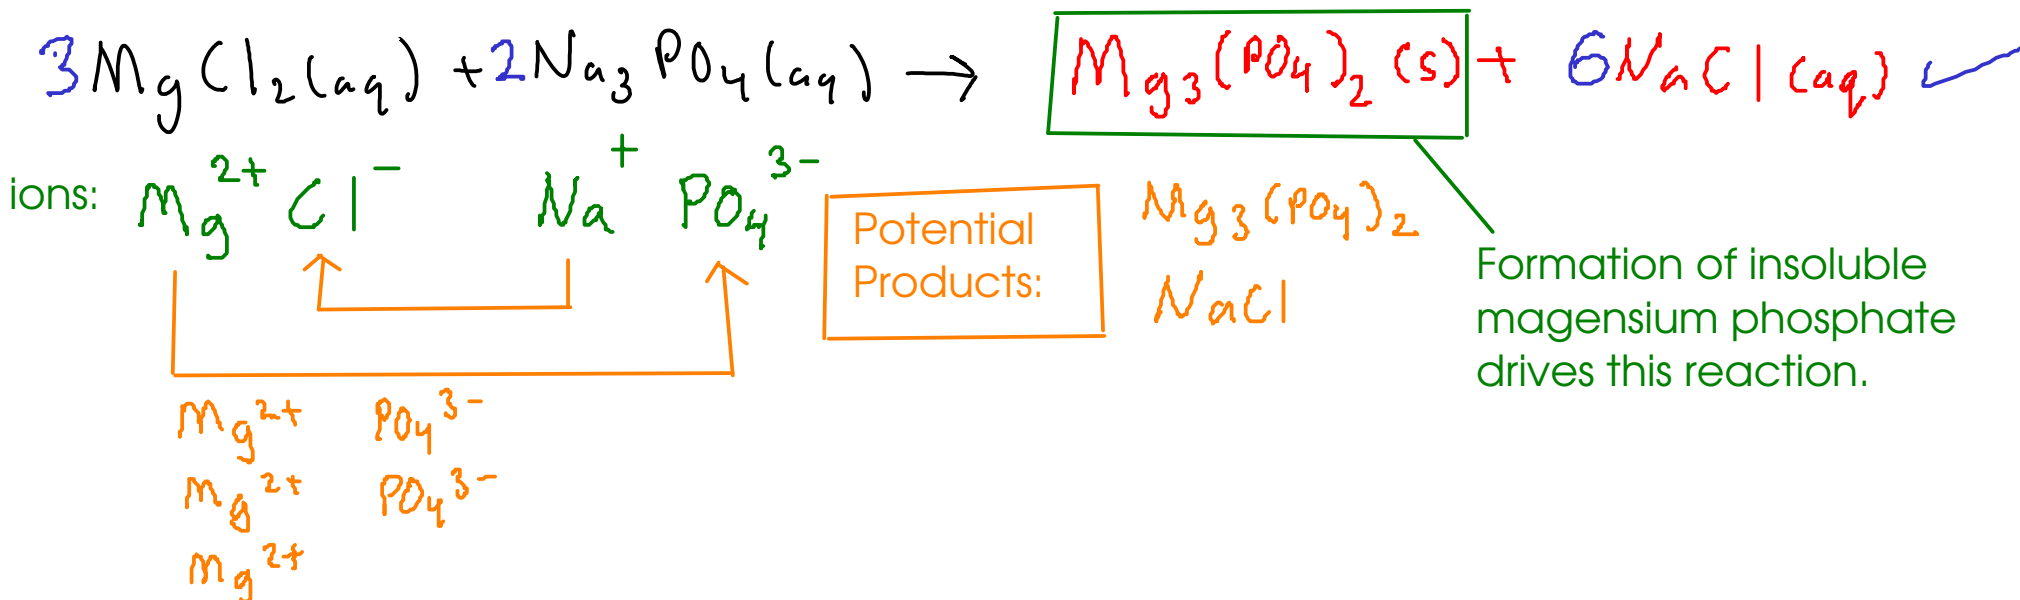

③ GAS FORMATION (formation of unstable molecules)

↑ SOME (but not all) reactions that form gases
are examples of exchange chemistry.

Just because you mix together two ionic compounds does NOT mean that a reaction will occur. You need a DRIVING FORCE for a reaction.

118 PRECIPITATION REACTIONS

- driving force is the formation of an insoluble ionic compound.

When you're trying to complete a precipitation reaction:

- ① Write the IONS that form when the reactants are dissolved.
- ② Make NEW compounds by pairing up cations with anions. Don't forget that the positive and negative charges must balance each other out!
- ③ Use the solubility rules to determine the PHASE of each new compound - solid or aqueous.
- ④ Balance the overall equation.

$\text{Mg}(\text{C}_2\text{H}_3\text{O}_2)_2$... dissolves in water

NaCl ... dissolves in water

So, no solid forms here. All possible combinations of these four ions result in compounds that dissolve readily in water.

NO CHANGE, therefore NO DRIVING FORCE, and NO REACTION

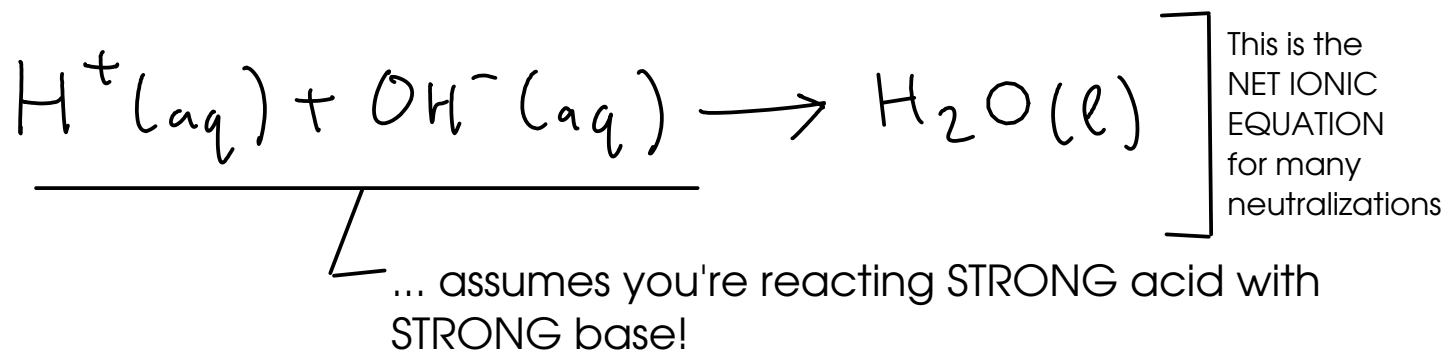

* We will learn about other driving forces than the formation of solid, but these driving forces do not apply to this reaction

ACID/BASE REACTIONS (also called NEUTRALIZATION REACTIONS)

- There are several stable molecules that may be formed in double replacement reactions, but the most common is WATER!
- Double replacement reactions that form water are also called "neutralizations"

* To make water (H₂O), you need a source of hydrogen ion (H⁺) and hydroxide ion (OH⁻)

ACIDS

- compounds that release hydrogen ion (H^+), when dissolved in water.

Properties of acids:

- Corrosive: React with most metals to give off hydrogen gas
- Cause chemical burns on contact
- Taste sour (like citrus - citric acid!)
- Changes litmus indicator to RED

BASES

- Substances that release hydroxide ion (OH^-) when dissolved in water

Properties of bases:

- Caustic: Attack and dissolve organic matter (think lye, which is NaOH)
- Cause skin/eye damage on contact
- Taste bitter
- changes litmus indicator to BLUE

Due to the dissolving action of base on your skin, bases will feel "slippery". The base ITSELF is not particularly slippery, but what's left of your skin IS!
