# ACKNOWLEDGEMENTS

First, I would like to thank the American Scandinavian Foundation in their support of my work. I would also like to thank Guðrún Marteinsdóttir for her coordination and advising, and Thorvaldur Gunlaugsson and Mette Mauritzen for their advising on my project for which this coding is intended to support. Lastly, I am very appreciative toward Gisli Víkingsson and Hafrannsóknastofnun for arranging a place for me to work.

# INTRODUCTION

With public access available for numerous satellite imaging products, modelling in atmospheric and oceanographic applications has become increasingly more prevalent.

Though there are numerous tools available for geospatial development, their use is more commonly applied towards mapping applications. With this being the case, there are a number of valuable texts for using these tools in such mapping applications [11] [1]; though, documentation for processing of remote sensing datasets is limited to brief contributions on personal blogs or manual pages and tutorials specific to one library or dataset. Python programming methods for performing such tasks will be focused on here, collecting various code and information from these text, blogs, etc. and presenting original code that may be employed in scripts to perform commonly required tasks in processing remote sensing data.

For a general place to get started with geospatial work with Python, Erik Westra's "Python Geospatial Development" is an excellent resource, and it will provide an excellent overview of geospatial work with python before looking at specific remote sensing datasets.

## 2.1 Geosetup

The tools presented here are collected into a Python program repository (currently under development) that will produce standardized gridded satellite data files that may be used as input for various models. This repository is publicly available on the collaborative coding site GitHub.

Link to repository on GitHub: <https://github.com/ryanjdillon/geosetup>

Or, you may [download the code as a zip-archive](#).

If you are interested in collaborating on this effort, please feel encouraged to fork the repository on GitHub and offer your contributions.

## 2.2 Improving this Documentation

There are many improvements that can always be made in either the code shown here, or the explanation of a particular approach to something. If you find something broken, or stuck with an inadequate explanation, feel free to contact me so that I might correct it.

Thanks, Ryan [ryanjamesdillon@gmail.com](mailto:ryanjamesdillon@gmail.com)

# BRIEF OVERVIEW OF COORDINATE SYSTEMS AND MAP PROJECTIONS

Before working with georeferenced datasets, it is important to understand how things can be referenced geographically.

Positions on earth's surface can be represented using different systems, the most accurate of these being **geodetic positions** determined by coordinates from a particular geographic coordinate system, or **geodetic system**.

In addition to coordinate systems, the assumed shape of the earth will affect how coordinate positions are translated to earth's surface. **Geodetic Datums** are mathematical definitions of for the shape of the earth, which in turn defines a geodetic system.

## 3.1 Coordinate Systems

Coordinate systems are categorized into two groups, both of which being commonly used in representing remote sensing data:

- **unprojected coordinate systems** these are 3-dimensional coordinate systems, such as latitude and longitude (referred to as *Geographic Coordinate System* in common GIS software)
- **projected coordinate systems** these are 2-dimensional, there are many all of which having an advantage over another for a particular use.

Either system may be used depending on the data format (e.g. *netCDF HDF* containing arrays of unprojected data vs. *GeoTIFF* images containing projected data). When working with multiple datasets, or doing some processing of a dataset, you may need to change between different coordinate systems.

Most often data will coincide with a latitude and longitude (i.e. unprojected). If it is desired to interpolate or re-sample this data, transforming the data to a projected system allows for simpler and a greater variety of methods to be used.

## 3.2 Earth's Shape and Datums

It is often easiest to make the assumption that the earth is a perfect sphere when working with spherical coordinates. However, the earth's shape is in fact an oblate ellipsoid, with its polar radius being approximately 21 km less than the equatorial radius [9].

This shape has been calculated using different systems for both the entire globe and for regional areas, known as *datums*.

The most widely used datum for Geographic Information Systems is the **World Geodetic System (WGS84)**, which is used by most Global Positioning System (GPS) devices by default.

It is important to know which datum was used to record positions of data, as there can be sizable differences between actual physical position of points with the same coordinates, depending on the datum.

## 3.3 Map Projections

In order to better visualise the earth's surface and simplify working with certain geographic information, 2-dimensional representations can be calculated using various mathematical transformations.

Depending on the size of the area of interest (i.e. a small coastal area vs. an entire ocean) different projections will provide the greatest accuracy when interpolation of data is necessary.

### 3.3.1 Mercator

The [Mercator Projection](#) is commonly used for general mapping applications where visualization is a priority over accuracy of size and shape near the poles. Variations of it are used for mapping applications, such as is used for Google Maps [15].

Though useful for many mapping applications, this projection should be avoided when interpolation of data is necessary due to increasing distortion error near the poles.

### 3.3.2 UTM

The [Universal Transverse Mercator \(UTM\) projection](#) is a variation of the Mercator projection, which uses a collection of different projections of 60 zones on the earth's surface to allow accurate positioning and minimal distortion on a 2-dimensional projection [8].

Though this system provides a way of accurate approach to a Mercator, it becomes difficult to work with when the area of interest spans multiple zones.

Figure 3.1: Mercator projection with Tissot circles showing increased distortion near the poles [5].

Figure 3.2: Universal Transverse Mercator (UTM) projection displaying the different zones [8]

### 3.3.3 Albers Equal-Area

The Albers equal-area conic projection is a projection that is useful where area needs to be preserved for large geographical areas. When working with data, as is needed when interpolating data over such an area.

Figure 3.3: Albers Equal-Area Conic projection with Tissot circles [5].

# GETTING STARTED WITH OCEAN COLOR AND BATHYMETRIC DATA

The datasets that will be focussed on are those containing parameters that are most generally applicable to marine ecosystem modeling: sea surface temperature, chlorophyll a, and bottom depth. The concepts and methods used for these may be extrapolated to other datasets, and should provide a good framework for processing such data.

## 4.1 Data Formats

### 4.1.1 netCDF HDF

The most common formats used for oceanographic and atmospheric datasets are Unidata's [Network Common Data Form \(netCDF\)](#) and HDF Group's [Hierarchical Data Format \(HDF\)](#) [18] [20].

Both of these formats have gone through multiple revisions, with different functionality and backwards compatibility being available between versions, with the latest versions being in most common use, netCDF-4 and HDF5 respectively.

As the name describes, HDF is hierarchical in its internal organization, which has many advantages particularly advanced organization of data and efficient storage and access to large amounts of data. HDF5 is the most current and widely used HDF format with many tools and libraries for accessing and creating datasets in this format.

### 4.1.2 GeoTIFF

Another common format for geospatial data is in the form of raster data, or data that is represented by grid cells particularly in the form of an image, such as [GeoTIFF](#) files.

The GeoTIFF format is a standardized file format, which is a modification of the Tagged Image File Format (TIFF) specially suited for storing datasets referenced in a projected coordinate system. Each data value will correspond to a grid cell (i.e. pixel) of the image, which is saved as a *tag* as metadata together with the image data [10]. The images pixel corresponds to an area enclosed by geographic boundaries defined by the projection used to create that GeoTIFF.

### 4.1.3 Arc/Info ASCII Grid and Binary Grid

Due to the popularity of ESRI's ArcGIS software, another format commonly seen is Arc/Info ASCII grid format and binary grid format. Developed by ESRI for their ArcGIS software, both formats store data in a similar way to GeoTIFF in that they relate a set of data values to grid cell areas, defined by some geographic bounds.

The binary format is a proprietary format that was developed to add functionality and prevent unlicensed use of data produced by their software.

The Arc/Info ASCII Grid is a simple ASCII text file format that is still found in used by some due to its simple non-proprietary format. The ASCII format includes a series of header rows defining the rows and columns in the grid, position of the center and corners, cell size, fill value for missing data, and then space-delimited values. As described by the Oak Ridge National Laboratory site [17]:

```
<NCOLS xxx>
<NROWS xxx>
<XLLCENTER xxx | XLLCORNER xxx>
<YLLCENTER xxx | YLLCORNER xxx>
<CELLSIZE xxx>
{NODATA_VALUE xxx}
row 1
row 2
.
.
.
row n
```

---

**Note:** There are many other raster image formats besides GeoTIFF and Arc/Info grid formats that geospatial data can be stored in. The GDAL libraries are capable of working with most of them, a list of which can be [found here](#) [19].

---

## 4.2 Data Properties

### 4.2.1 Data Levels

In some instances one may want to perform their own processing of raw satellite data, but for our purposes here, we will just be concerned with working with data that has already been evaluated for quality and averaged into regular time allotments.

It is useful to be familiar with the different types of 'levels' that are available, so that you may select the proper data to begin working with [16]:

Level	Code	Description
Level 0	L0	Raw instrument data
Level 1A	L1A	Reconstructed raw instrument data
Level 1B	L1B	Products containing geolocated and calibrated spectral radiance and solar irradiance data
Level 2	L2	Products derived from the L1B product. One file per orbit
Level 3	L3	Averaged global gridded products, screened for bad data points
Level 4	L4	Model output; derived variables

With this information, we can see that we are most interested in the Level 3 (L3) data sets.

## 4.3 Focus Datasets

The datasets that will be covered are those for which methods have been written in `Geosetup`.

For data that is accessible via an FTP server, any standard FTP-client can be used for downloading the data (e.g. `Filezilla`) [6]. On UNIX-like systems this can more easily be done by using the `wget` command.

### 4.3.1 Pathfinder

`Pathfinder` is a merged data product from the National Oceanographic Data Center (NODC) [23], an office of the National Oceanic and Atmospheric Association (NOAA).

#### Summary

- *Data Format:* HDF5
- *Date Range:* 1981-2011 (gap from 1994-05-27 to 1995-07-01)
- *Timestamps:* in days from reference time ‘1981-01-01 00:00:00’
- *Data quality control:* variable containing quality flags for data points

#### Variables in Dataset

#### Downloading

Pathfinder data is available to download via [HTTP](#), [FTP](#), [THREDDS](#) (supporting OPeNDAP), and rendered [images/KML](#) [23].

#### Example for downloading all Pathfinder v5.2 data for 2007:

```
wget -r -np -nH ftp://ftp.nodc.noaa.gov/pub/data.nodc/pathfinder/Version5.2/2007
```

Name	Long Name	Type
20070501013213-NODC-L3C ...	20070501013213-NODC-L3C_GHRSSST-SSTskin-AVHRR_Pathfi...	Local File
aerosol_dynamic_indicator	aerosol dynamic indicator	[lon][lat]
dt_analysis	Deviation from last SST analysis	[lon][lat]
l2p_flags	L2P flags	[lon][lat]
lat	latitude	—
lon	longitude	—
pathfinder_quality_level	Pathfinder SST quality flag	[lon][lat]
quality_level	SST measurement quality	[lon][lat]
sea_ice_fraction	sea ice fraction	[lon][lat]
sea_surface_temperature	NOAA Climate Data Record of sea surface skin temperature	[lon][lat]
sses_bias	SSES bias estimate	[lon][lat]
sses_standard_deviation	SSES standard deviation	[lon][lat]
sst_dtime	time difference from reference time	[lon][lat]
time	reference time	—
wind_speed	10m wind speed	[lon][lat]

Figure 4.1: Panoply output showing datasets included in Pathfinder v5.2 datafile

## 4.3.2 CoRTAD

CoRTAD is a reprocessed weekly average dataset of the Pathfinder data, developed by National Oceanographic Data Center (NODC) [22] for modelling and management of coral reef systems.

### Summary

- *Data Format:* HDF5
- *Date Range:* 1981-2011 (gap from 1994-05-27 to 1995-07-01)
- *Timestamps:* in days from reference time ‘1981-01-01 00:00:00’
- *Data quality control:* Two separate data variables are included, including one where gaps due to clouds, etc. have been interpolated. Also included is an array of all bad data, and a variety of variables providing statistical evaluation of all data.

### Variables in Dataset

### Downloading

On UNIX-like systems, you may use a file with a list of the URL’s for all files you would like to download. Then you can use the `wget` command with the `-i` option to download all files in the list.

#### Example `cortad_wget-list.txt`

```
ftp://ftp.nodc.noaa.gov/pub/data.nodc/cortad/Version4/cortadv4_row01_col105.nc
ftp://ftp.nodc.noaa.gov/pub/data.nodc/cortad/Version4/cortadv4_row00_col109.nc
ftp://ftp.nodc.noaa.gov/pub/data.nodc/cortad/Version4/cortadv4_row01_col109.nc
```

#### Example `wget` command:

### 4.3.3 GlobColour Chlorophyll-a Data

The European Space Agency (ESA) produces a merged chlorophyll dataset that combines data acquired from the SeaWiFS (NASA), MODIS (NASA), and MERIS (ESA) satellite imaging missions.

A very extensive explanation of the data and its derivation is covered in the GlobColour Product User Guide. You may download it from their website here:

[http://www.globcolour.info/CDR\\_Docs/GlobCOLOUR\\_PUG.pdf](http://www.globcolour.info/CDR_Docs/GlobCOLOUR_PUG.pdf)

This merged data product is ideal for applications where your sampling period may extend beyond that covered by any one when your sampling period extends across the acquisition periods of each of the different missions offering imagery in a spectral range from which chlorophyll values may be processed from.

---

**Note:** See *Temporal ranges of ocean color satellite missions* for coverage of different datasets.

---

Different merging methods have been used, including:

- simple averaging
- weighted averaging
- GSM model

### Grid Formats

#### Integerized Sinusoidal (ISIN) L3b Product

- Angular resolution:  $1/24^\circ$  (approx.  $4.63\text{km}$  spatial resolution)
- Uses `rows` and `cols` arrays to specify the latitudinal and longitudinal index of the bins, stored in the product (i.e. mean chlorophyll values in `CHL1_mean`)

#### Plate-Carré projection (Mapped) L3m Product

- Angular resolution:  $0.25^\circ$  and  $1.0^\circ$
- latitude and longitude specifying the center of each cell

---

**Note:** The mapped (L3m) product is an easier format to work, as it uses standard coordinate and value organization, but you will need to use the ISIN grid (L3b) product if you require the  $\sim 4.63\text{ km}$  resolution.

---

## Summary

- *Data Format:* netCDF-3
- *Date Range:* 1981-2011 (gap from 1994-05-27 to 1995-07-01)
- *Timestamps:* in hours from reference time ‘1981-01-01 00:00:00’
- *Data quality control:* variable containing quality flags for data points

## Variables in Dataset

Name	Long Name	Type
▼ L3m_20070501_GLOB_25_GS...	L3m_20070501_GLOB_25_GSM-MERMODSWF_CHL1_DAY_00.nc	Local File

lat	latitude	—
lon	longitude	—

Figure 4.3: Panoply output showing datasets included in Globcolour datafile

## Downloading

Data can be downloaded for specific time periods and geographic extents through their gui download interface on the web:

<http://hermes.acri.fr/GlobColour/index.php>

ESA’s also maintains an ftp-server from which you may download GlobColour data in batch, for a large number of files.

### Example for downloading GSM averaged 1-Day Chlorophyll-a between 1997-2012:

```
wget -r -l10 -t10 -A "*.gz" -w3 -Q1000m \
ftp://globcolour_data:fg678@ftp.acri.fr/GLOB_4KM/RAN/CHL1/MERGED/GSM/{1997,1998}
```

## 4.3.4 GEBCO Bathymetric Data

The [General Bathymetric Chart of the Oceans](#) is a compilation of a ship depth soundings and satellite gravity data and images. Using quality-controlled data to begin with, values between sounded depths have been interpolated with gravity data obtained by satellites [13].

Source Identifier (SID) Grid describes which measurements are from soundings or predictions.

## Summary

- *Data Format:* netCDF-3
- *Angular resolution:* 30sec and 1° grids

- $(0, 0)$  position at northwest corner of file
- Grid pixels are center-registered
- **Data organization: Single data file for whole globe**
  - 21,600 rows x 43,200 columns = 933,120,000 data points
- *Units*: depth in meters. Bathymetric depths are negative and topographic positive
- *Date Range*: Dates of soundings vary. Most recent 2010
- *Data quality control*: separate file with SID grid of data sources and quality.

### Variables in Dataset

Name	Long Name	Type
▼  gebco_08.nc	gebco_08.nc	Local File
 dimension	dimension	—
 spacing	spacing	—
 x_range	x_range	—
 y_range	y_range	—
 z	z	—
 z_range	z_range	—

Figure 4.4: Panoply output showing datasets included in GEBCO datafile

### Downloading

Before downloading the GEBCO data, you must register at their website first. [Follow link to register](#)

After registration, you can [access the data here](#). You will have the option of downloading either the `gebco_08.nc` file for the *30sec* gridded data or the `gridone.nc` file for the  $1^\circ$ .

You may also download the SID grid which contains flags corresponding to each data point as to whether it is a sounding or interpolated, and the quality of each.

## 4.4 Previewing Data

Various applications are available for viewing netCDF and HDF formatted data, but not all are capable of opening versions of both formats such as both HDF5 and netCDF3.

When writing code to work with such data sets, it is often necessary to know the names and dimensions of variables within the datafile, which a viewing application makes particularly easy.

### 4.4.1 Panoply

Panoply is a viewer application developed by NASA that allows a number of useful tools for exploring data in netCDF, HDF, and GRIB formats.

---

**Note:** Panoply is dependent on the Java runtime environment, which must be installed before installing. [Download Java](#)

---

Panoply Download Link:

<http://www.giss.nasa.gov/tools/panoply/>

#### Some Neat Features

- Slice and plot data sets, combining them, and save to image files
- Connect to OPeNDAP and THREDDS data servers to explore data remotely
- Create animations from collection of images

### 4.4.2 VISAT Beam

The ESA had commissioned the development [BEAM](#) of an open-source set of tools for viewing, analyzing and processing a large number of different satellite data products [14]. In addition they have developed the GUI desktop application VISAT for using these tools

[Download LSAT/BEAM](#)

### 4.4.3 Quantum GIS

[Quantum GIS](#) is an open source GIS application that is available for all major operating systems and has features similar to those found in much more costly GIS applications.

It is an excellent resource when viewing images created by your scripts, and has the ability to be extended with [PyQGIS](#) once you become familiar with Python and working with geospatial data.

[Download Quantum GIS](#)

# GETTING STARTED WITH PYTHON

---

## Quickstart

*Skip to installation and package guide*

---

If you have previous experience programming, learning Python is a fairly intuitive process with syntax that is easily read and remembered compared to other lower level languages like C/C++.

A good place to start is with Google's free online python course:

<https://developers.google.com/edu/python/>

## 5.1 Science and Python

Along with gaining a general familiarity in Python, you will want to become familiar with the use of NumPy, as this module is used extensively for working with large datasets in an efficient manner. In addition the netCDF4 module that is used here for opening netCDF and HDF datasets by default creates masked NumPy array when importing these datasets.

The SciPy team has a great NumPy tutorial to get started with:

[http://www.scipy.org/Tentative\\_NumPy\\_Tutorial](http://www.scipy.org/Tentative_NumPy_Tutorial)

Though not really covered in this article, the Python Data Analysis Library (Pandas) has incredible tools for data processing and working with statistical analysis and modelling. In combination together, Python, NumPy/SciPy, and Pandas offers a powerful data processing ability, rivalling R and Matlab with functionality that does not exist in either .

## 5.2 Troubleshooting

iPython is an excellent tool for working interactively with python, allowing you to test code, play with concepts you are exploring, and store various information in a workspace similar to R and Matlab work flows [2] [21].

When hitting stumbling blocks or just trying to improve your code, StackOverflow is a fantastic resource for receiving support and finding existing solutions to your problems.

## 5.3 Important things to consider

- Backup! In more than two places preferably. It takes a long time to code, and you don't want to start over if something happens.
- Along with general backups, using a version control system such as [Git](#), [Subversion](#), or [Mercurial](#). Doing so allows you to easily revert to previous versions of your code, collaborate with others, track problems, develop in stages, and more.
- Stick to the conventions: coding like everybody else (e.g. naming, spacing, commenting, etc.) makes things easier for you and for others to work with your code.

## 5.4 Setting up your development environment

The code here was developed using Python version 2.7; however it should be compatible with versions greater the 2.6.

### 5.4.1 Installing Python

Python can be [downloaded from Python.org](#) as source, as well as binary installers for Windows and Mac OSX.

Most distributions of Linux come with Python pre-installed. To see what version of python you are running, run the following from the command line `python -V`.

### 5.4.2 Additional Python Packages you will need

In order to properly run the code presented here, you will need to also install a number of other libraries/packages that are used.

It will just be assumed that if you are using another distribution of Linux/UNIX than Ubuntu, that you will be familiar enough to hunt down the packages/source and install them.

- **gdal**
  - Ubuntu (linux): <https://launchpad.net/~ubuntugis/+archive/ppa/>
  - Windows: Install OSGeo (with GDAL): <http://trac.osgeo.org/osgeo4w/wiki>
  - Mac OSX: Pre-compiled binaries [http://www.kyngchaos.com/software/frameworks#gdal\\_com](http://www.kyngchaos.com/software/frameworks#gdal_com)
- **pyroj**
  - Ubuntu (linux): <http://packages.ubuntu.com/search?keywords=python-pyproj>
  - Windows: <http://code.google.com/p/pyproj/downloads/list>
  - Mac OSX (Unverified): <http://mac.softpedia.com/get/Math-Scientific/pyproj.shtml>

- **numpy**
  - Ubuntu (linux): from command line `sudo apt-get install python-numpy`

### 5.4.3 Getting Geosetup

In order to collaborate to the code, it is preferable that you obtain the Geosetup code by forking the repository from GitHub.

If you're new to Git, a comprehensive instructional book is [available here](#) [3]:

If you prefer you may [download the code as a ZIP archive](#), or access it from the [repository page on GitHub](#).

# IMPORTING NETCDF AND HDF DATA WITH PYTHON

The first thing you'll need to do to work with these datasets is to import it to

## 6.1 netCDF4

`netCDF4` is a python package that utilizes NumPy to read and write files in netCDF and HDF formats [12]. It contains methods that allow the opening and writing of netCDF4, netCDF3 and HDF5 files.

Before importing the data, you'll want to find the name of the dataset variable that you want to import. You can determine this by first opening the file with *Panoply* and checking the name of the variable. Examples for the different variables available from this paper's focus datasets is found in the summaries sections of *Focus Datasets*.

### Example showing the data import using netCDF4:

```
import numpy as np
import netCDF4 as Dataset

filepath = /path/to/file.nc
# Read in dataset (using 'r' switch, 'w' for write)
dataset = Dataset(filepath, 'r')
# Copy data to variables, '[' also copies missing values mask
lons = dataset.variables["lon"][:]
lats = dataset.variables["lat"][:]
sst = dataset.variables["sea_surface_temperature"][:]
dataset.close()
```

When data is copied to a variable in Python, it places it all into the systems temporary memory, which means there is a limit as to how much data can be loaded. With certain datasets, the dataset variables may be large enough to exceed the system memory.

Typically these datasets cover much larger geographic areas than are interested in (i.e. the whole earth), so it is possible to load only the data for the area of interest.

```
1     def getnetcdfdata(data_dir, nc_var_name, min_lon, max_lon, min_lat, max_lat, data_time_start, data_time_e
2     '''Extracts subset of data from netCDF file
3
4     based on lat/lon bounds and dates in the iso format '2012-01-31' '''
5
6     # Create list of data files to process given date-range
```

```
7     file_list = np.asarray(os.listdir(data_dir))
8     file_dates = np.asarray([datetime.datetime.strptime(re.split('-', filename)[0], '%Y%m%d%H%M%S') for filename in file_list])
9     data_files = np.sort(file_list[(file_dates >= data_time_start)&(file_dates <= data_time_end)])
10
11     # Get Lat/Lon from first data file in list
12     dataset = Dataset(os.path.join(data_dir, file_list[0]), 'r')
13     lons = dataset.variables["lon"][:]
14     lats = dataset.variables["lat"][:]
15
16     # Create indexes where lat/lons are between bounds
17     lons_idx = np.where((lons > math.floor(min_lon)) & (lons < math.ceil(max_lon)))[0]
18     lats_idx = np.where((lats > math.floor(min_lat)) & (lats < math.ceil(max_lat)))[0]
19     x_min = lons_idx.min()
20     x_max = lons_idx.max()
21     y_min = lats_idx.min()
22     y_max = lats_idx.max()
23
24     # Create arrays for performing averaging of files
25     vals_sum = np.zeros((y_max-y_min + 1, x_max-x_min + 1))
26     vals_sum = ma.masked_where(vals_sum < 0, vals_sum)
27     mask_sum = np.empty((y_max-y_min + 1, x_max-x_min + 1))
28     dataset.close()
29
30     # Get average of chlorophyll values from date range
31     file_count = 0
32     for data_file in data_files:
33         current_file = os.path.join(data_dir, data_file)
34         dataset = Dataset(current_file, 'r') # by default numpy masked array
35         vals = np.copy(dataset.variables[nc_var_name][0, y_min:y_max + 1, x_min:x_max + 1])
36         #vals = ma.masked_where(vals < 0, vals)
37         #ma.set_fill_value(vals, -999)
38         vals = vals.clip(0)
39         vals_sum += vals
40         file_count += 1
41         dataset.close()
42     vals_mean = vals_sum/file_count #TODO simple average
43
44     # Mesh Lat/Lon the unravel to return lists
45     lons_mesh, lats_mesh = np.meshgrid(lons[lons_idx], lats[lats_idx])
46     lons = np.ravel(lons_mesh)
47     lats = np.ravel(lats_mesh)
48     vals_mean = np.ravel(vals_mean)
49
50     return lons, lats, vals_mean
```

Another option for avoiding this problem is by loading the data in chunks, using sparse arrays, or python libraries that allow loading the data onto the system hard drive, such as [PyTables](#) or [h5py](#).

### 6.1.1 OPeNDAP & THREDDS

Rather than opening the data from files on your local machine, it is possible to open them remotely. Rather than creating the dataset from a local data file path, you simply reference the path to a file on a remote OPeNDAP or THREDDS server.

To create a dataset for data located at [http://data.nodc.noaa.gov/opendap/pathfinder/Version5.2/1981/19811101025755-NODC-L3C\\_GHRSSST-S](http://data.nodc.noaa.gov/opendap/pathfinder/Version5.2/1981/19811101025755-NODC-L3C_GHRSSST-S) you would simply do the following:

```
1     import numpy as np
2     import netCDF4 as Dataset
3
4     filepath = 'http://data.nodc.noaa.gov/opendap/pathfinder/Version5.2/1981/19811101025755-NODC-L3C_GHRSSST-S'
5     # Read in dataset (using 'r' switch, 'w' for write)
6     dataset = Dataset(filepath, 'r')
```

For further information on these protocols, thorough explanations are presented on their websites.

OPeNDAP

THREDDS

# WORKING WITH PROJECTIONS USING PYTHON

## 7.1 pyproj

`pyproj` is a python interface to the [PROJ.4](#) library which offers methods for working between geographic coordinates (e.g. latitude and longitude) and Cartesian coordinates (i.e. two dimensional projected coordinates - x,y) [4].

### 7.1.1 Defining variables from pyproj class instances

It is possible to extract information from `pyproj` ellipsoid and projection class instances if needed for other calculations.

As an example, let us first define an ellipsoid using the WGS84 datum:

```
g = pyproj.Geod(ellps='WGS84')
```

If we were to want to use the radius of the earth of this ellipsoid for another calculation, we could extract the value to a variable from the `pyproj` ellipsoid class instance we defined above.

To find the value, you can use the `dir()` function to find the names that are defined by a module. We can see by the following that the first variable listed (i.e. not an `__attribute__`) is `a`:

```
dir(g)
>>> dir(g)
['__class__', '__delattr__', '__dict__', '__doc__', '__format__', '__getattribute__',
```

You may access these by using either `getattr` function (if you have the property name as a string or would like to access it dynamically) or more simply when we know the name of the property by just using the dot notation:

```
>>> getattr(g,'a') # getattr function
6378137.0
```

```
>>> g.a # dot notation
6378137.0
```

If we hadn't already known that `a` was the value we were looking for, we could have just used the dot notation as above to have output the various values that were available in this object.

To make things easier to read later, you could do the following:

```
earth_equa_radius = g.a # earth's radius at the equator in meters
earth_pole_radius = g.b # earth's radius through poles in meters
```

### 7.1.2 Defining a projection

Example of defining a projection using the EPSG code:

```
import pyproj

# LatLon with WGS84 datum used by GPS units and Google Earth
wgs84 = pyproj.Proj(init='EPSG:4326')

# Lambert Conformal Conical (LCC)
lcc = pyproj.Proj(init='EPSG:3034')
```

Not all projections are available by using the EPSG reference code, but it is possible to define your own projection using `pyproj` and `gdal` in python.

[Spatialreference](#) is a great resource for finding the details for the projection you'd like to create (assuming it's just not in the library; though, feel free to define a completely custom projection).

Example of defining the Albers projection:

```
# Albers Equal Area Conic (aea)
nplaeal = pyproj.Proj("+proj=laea +lat_0=90 +lon_0=-40 +x_0=0 +y_0=0 \
+ellps=WGS84 +datum=WGS84 +units=m +no_defs")
```

# GRIDDING AND RESAMPLING DATA WITH PYTHON

When using remote sensing data for model applications, you will want to somehow standardize everything to a uniform grid. Your data may be scattered, and the satellite data be arranged at different resolutions and grids (and perhaps using different projections).

## 8.1 Deciding what to do

### 8.1.1 Choosing an Interpolation Method

Depending on the type of data that you will be re-sampling to a grid, different interpolation methods may be better suited to your data.

It is possible to interpolate data referenced by an unprojected coordinate system; though, due to more complicated calculations involved and potential differences in the datasets, it may be easiest to first project the data. The type of projection that is chosen to project the data to before interpolating it using a 2-dimensional interpolation method depends upon the extent of the study area and latitudes at which the data exist.

### 8.1.2 Choosing a Cartesian Projection

In general, you should attempt to choose a projection that does not distort the area over which the area exists, introducing error in your interpolation product, such as using the Albers Equal Area projection for a large area extending into northern latitudes (e.g. the North Atlantic ocean) (see *Map Projections*).

## 8.2 Gridding

Before interpolating the data to a new grid, you will want to create that grid, defined by latitude and longitude coordinates.

## 8.2.1 Creating a grid

Create Grid:

```
import numpy as np

def creategrid(min_lon, max_lon, min_lat, max_lat, cell_size_deg, mesh=False):
    '''Output grid within geobounds and specific cell size

    cell_size_deg should be in decimal degrees'''

    min_lon = math.floor(min_lon)
    max_lon = math.ceil(max_lon)
    min_lat = math.floor(min_lat)
    max_lat = math.ceil(max_lat)

    lon_num = (max_lon - min_lon)/cell_size_deg
    lat_num = (max_lat - min_lat)/cell_size_deg

    grid_lons = np.zeros(lon_num) # fill with lon_min
    grid_lats = np.zeros(lat_num) # fill with lon_max
    grid_lons = grid_lons + (np.asarray(range(lon_num))*cell_size_deg)
    grid_lats = grid_lats + (np.asarray(range(lat_num))*cell_size_deg)

    grid_lons, grid_lats = np.meshgrid(grid_lons, grid_lats)
    grid_lons = np.ravel(grid_lons)
    grid_lats = np.ravel(grid_lats)

    #if mesh = True:
    #    grid_lons = grid_lons
    #    grid_lats = grid_lats

    return grid_lons, grid_lats
```

## 8.3 Re-sampling to Grid

### 8.3.1 Without Projecting

It is possible to take the geographic coordinates and interpolate them over a spherical surface, rather than first projecting the data, and then performing the interpolation on a 2-dimensional surface. This can be done using `scipy.interpolator.RectSphereBivariateSpline`'s smoothing spline approximation:

```
import numpy as np
from scipy.interpolate import RectSphereBivariateSpline

def geointerp(lats, lons, data, grid_size_deg, mesh=False):
    '''We want to interpolate it to a global x-degree grid'''
    deg2rad = np.pi/180.
    new_lats = np.linspace(grid_size_deg, 180, 180/grid_size_deg)
    new_lons = np.linspace(grid_size_deg, 360, 360/grid_size_deg)
    new_lats_mesh, new_lons_mesh = np.meshgrid(new_lats*deg2rad, new_lons*deg2rad)

    '''We need to set up the interpolator object'''
    lut = RectSphereBivariateSpline(lats*deg2rad, lons*deg2rad, data)

    '''Finally we interpolate the data. The RectSphereBivariateSpline
    object only takes 1-D arrays as input, therefore we need to do some reshaping.'''
    new_lats = new_lats_mesh.ravel()
    new_lons = new_lons_mesh.ravel()
    data_interp = lut.ev(new_lats, new_lons)

    if mesh == True:
```

```
data_interp = data_interp.reshape((360/grid_size_deg,  
                                  180/grid_size_deg)).T  
  
return new_lats/deg2rad, new_lons/deg2rad, data_interp
```

### Limitations:

- This method is restricted to using the smoothing spline approximation, which may not be the best method for your data
- It assumes a spherical earth, where using the WGS84 datum would more accurately represent the data on the ellipsoid earth.

# PLOTTING WITH PYTHON

## 9.1 Matplotlib and Basemap

`Matplotlib` is a versatile plotting library that was developed by [John Hunter](#) that may be used for everything from basic scatter plots to cartographic plots, along with remote sensing data.

`Matplotlib basemap` is an additional library to `matplotlib` which may be used for plotting maps and 2-dimensional data on them. It performs similar functionality to `pyproj` (and uses the same PROJ.4 libraries) to transform data to 2-dimensional projections.

### 9.1.1 Introduction

A collection of `matplotlib.basemap` example plotting scripts can be [found here](#).

Just to get an idea, let's say we want to plot a map of Iceland in the Albers Conic Conformal projection

```
1     from mpl_toolkits.basemap import Basemap
2     import matplotlib.pyplot as plt
3     import numpy as np
4
5     mapWidth = 600000
6     mapHeight = 600000
7     lat0center = 64.75
8     lon0center = -18.60
9
10    m = Basemap(width=mapWidth,height=mapHeight,
11              rsphere=(6378137.00,6356752.3142),\
12              resolution='f',area_thresh=1000.,projection='lcc',\
13              lat_1=45.,lat_2=55.,\
14              lat_0=lat0center,lon_0=lon0center)
15
16    # Draw parallels and meridians.
17    m.drawparallels(np.arange(-80.,81.,1.), labels=[1,0,0,0], fontsize=10)
18    m.drawmeridians(np.arange(-180.,181.,1.), labels=[0,0,0,1], fontsize=10)
19    m.drawmapboundary(fill_color='aqua')
20    m.drawcoastlines(linewidth=0.2)
21    m.fillcontinents(color='white', lake_color='aqua')
22    plt.show()
```

If you would like to plot data points on a map, and have the points show as increasingly larger markers, with increasing values, here is how you do it:

Figure 9.1: Plot of Iceland using matplotlib's basemap library with one degree parallels and meridians.

```
1 def plotSizedData(map_obj, lons, lats, values, symbol, min_size, max_size, lines=False):
2     '''
3     Plot data with varying sizes
4     '''
5     proj_x, proj_y = m(lons, lats)
6
7     # Calculate marker sizes using y=mx+b
8     # where y = marker size and x = data value
9     slope = (max_size-min_size)/(max(values)-min(values))
10    intercept = min_size-(slope*min(values))
11
12    for x, y, val in zip(proj_x, proj_y, values):
13        msize = (slope*val)+intercept
14        map_obj.plot(x, y, symbol, markersize=msize)
```

To automatically center a map projected in a conic conformal projection, the following function will determine the correct center latitude, longitude, and proper width and height to encompass the data. You may also pass a scale to the function to make the width and height a desired percentage larger than the minimum plot area, so that there is a margin around the outermost points on the plot.

```
1 def centerMap(lons, lats, scale):
2     '''
3     Set range of map. Assumes -90 < Lat < 90 and -180 < Lon < 180, and
4     latitude and longitude are in decimal degrees
5     '''
6     north_lat = max(lats)
7     south_lat = min(lats)
8     west_lon = max(lons)
9     east_lon = min(lons)
10
11    # find center of data
12    # average between max and min longitude
13    lon0 = ((west_lon-east_lon)/2.0)+east_lon
14
15    # define ellipsoid object for distance measurements
16    g = pyproj.Geod(ellps='WGS84') # Use WGS84 ellipsoid TODO make variable
17    earth_radius = g.a # earth's radius in meters
18
19    # Use pythagorean theorem to determine height of plot
20    # divide b_dist by 2 to get width of triangle from center to edge of data area
21    # inv returns [0]forward azimuth, [1]back azimuth, [2]distance between
22
23    # a_dist = the height of the map (i.e. mapH)
24    b_dist = g.inv(west_lon, north_lat, east_lon, north_lat)[2]/2
25    c_dist = g.inv(west_lon, north_lat, lon0, south_lat)[2]
26
27    mapH = pow(pow(c_dist,2)-pow(b_dist,2),1./2)
28    lat0 = g.fwd(lon0, south_lat, 0, mapH/2)[1]
29
30    # distance between max E and W longitude at most southern latitude
31    mapW = g.inv(west_lon, south_lat, east_lon, south_lat)[2]
32
33    return lon0, lat0, mapW*scale, mapH*scale
```

# WRITING GEOSPATIAL DATA TO FILES

Say you want to take the data that you have been working on, maybe do some calculations on, and put it into a file that you can import into a GIS application such as ArcGIS or Quantum GIS. This could be done by writing the data to a text format, such as ESRI's ASCII grid format, but a more efficient way of doing this is by writing it to a GeoTIFF format using the bindings for GDAL libraries (TODO link).

## 10.1 Write file function

Imports:

```
1 import numpy as np
2 import gdal
3 import os
4 from osgeo import gdal
5 from osgeo import osr
6 from osgeo import ogr
7 from osgeo.gdalconst import *
8 import pyproj
9 import scipy.sparse
10 import scipy
11 gdal.AllRegister() #TODO remove? not necessary?
12 gdal.UseExceptions()
```

GeoPoint Class for transforming points and writing to raster files:

```
1 class GeoPoint:
2     '''Transform coordinate system, projection, and write geospatial data'''
3
4     """lon/lat values in WGS84"""
5     # LatLon with WGS84 datum used by GPS units and Google Earth
6     wgs84 = pyproj.Proj(init='EPSG:4326')
7     # Lambert Conformal Conical (LCC)
8     lcc = pyproj.Proj(init='EPSG:3034')
9     # Albers Equal Area Conic (aea)
10    nplaea1 = pyproj.Proj("+proj=laea +lat_0=90 +lon_0=-40 +x_0=0 +y_0=0 \
11        +ellps=WGS84 +datum=WGS84 +units=m +no_defs")
12    # North pole LAEA Atlantic
13    nplaea2 = pyproj.Proj(init='EPSG:3574')
14    # WGS84 Web Mercator (Auxillary Sphere; aka EPSG:900913)
15    # Why not to use the following: http://gis.stackexchange.com/a/50791/12871
16    web_mercator = pyproj.Proj(init='EPSG:3857')
17    # TODO add useful projections, or hopefully make automatic
18
```

```
19     def __init__(self, x, y, vals, inproj=wgs84, outproj=nplaea,
20                  cell_width_meters=50., cell_height_meters=50.):
21         self.x = x
22         self.y = y
23         self.vals = vals
24         self.inproj = inproj
25         self.outproj = outproj
26         self.cellw = cell_width_meters
27         self.cellh = cell_height_meters
28
29     def __del__(self):
30         class_name = self.__class__.__name__
31         print class_name, "destroyed"
32     def transform_point(self, x=None, y=None):
33         if x is None:
34             x = self.x
35         if y is None:
36             y = self.y
37         return pyproj.transform(self.inproj, self.outproj, x, y)
38
39
40     def get_raster_size(self, point_x, point_y, cell_width_meters, cell_height_meters):
41         """Determine the number of rows/columns given the bounds of the point
42         data and the desired cell size"""
43         # TODO convert points to 2D projection first
44
45         cols = int(((max(point_x) - min(point_x)) / cell_width_meters)+1)
46         rows = int(((max(point_y) - min(point_y)) / abs(cell_height_meters))+1)
47
48         print 'cols: ', cols
49         print 'rows: ', rows
50
51         return cols, rows
52
53
54     def create_geotransform(self, x_rotation=0, y_rotation=0):
55         '''Create geotransformation for converting 2D projected point from
56         pixels and inverse geotransformation to pixels (what I want, but need the
57         geotransform first).'''
58
59         # TODO make sure this works with negative & positive lons
60         top_left_x, top_left_y = self.transform_point(min(self.x),
61                                                       max(self.y))
62
63         lower_right_x, lower_right_y = self.transform_point(max(self.x),
64                                                             min(self.y))
65         # GeoTransform parameters
66         # --> need to know the area that will be covered to define the geo transform
67         # top left x, w-e pixel resolution, rotation, top left y, rotation, n-s pixel resolution
68         # NOTE: cell height must be negative (-) to apply image space to map
69         geotransform = [top_left_x, self.cellw, x_rotation,
70                        top_left_y, y_rotation, -self.cellh]
71
72         # for mapping lat/lon to pixel
73         success, inverse_geotransform = gdal.InvGeoTransform(geotransform)
74         if not success:
75             print 'gdal.InvGeoTransform(geotransform) failed!'
76             sys.exit(1)
77
78         return geotransform, inverse_geotransform
```

### Convert coordinate to pixel:

```
1     def point_to_pixel(self, point_x, point_y, inverse_geotransform):
2         """Translates points from input projection (using the inverse
3         transformation of the output projection) to the grid pixel coordinates in data
4         array (zero start)"""
5
6         # apply inverse geotransformation to convert to pixels
7         pixel_x, pixel_y = gdal.ApplyGeoTransform(inverse_geotransform,
8                                                    point_x, point_y)
9
10        return pixel_x, pixel_y
```

Convert pixel to coordinate:

```
1     def pixel_to_point(self, pixel_x, pixel_y, geotransform):
2         """Translates grid pixels coordinates to output projection points
3           (using the geotransformation of the output projection)"""
4
5         point_x, point_y = gdal.ApplyGeoTransform(geotransform, pixel_x, pixel_y)
6     return point_x, point_y
```

Write data to raster file:

```
1     def create_raster(self, in_x=None, in_y=None, filename="data2raster.tiff",
2 output_format="GTiff", cell_width_meters=1000., cell_height_meters=1000.):
3         '''Create raster image of data using gdal bindings'''
4         # if coords not provided, use default values from object
5         if in_x is None:
6             in_x = self.x
7         if in_y is None:
8             in_y = self.y
9
10        # create empty raster
11        current_dir = os.getcwd()+'/'
12        driver = gdal.GetDriverByName(output_format)
13        number_of_bands = 1
14        band_type = gdal.GDT_Float32

24     geo_obj.create_raster()
```

## GEOSETUP - TEXTDATA

This module can be modified to any comma separated value or text file data set That you would like to import alongside remote sensing data you have imported. Currently it is configured to import a dataset of sight surveying data, assigning data types and sizes to the various columns in the dataset.

Imports:

```
1 import numpy as np
2 from netCDF4 import Dataset
3 import sys, os
4 from StringIO import StringIO
5 import datetime
```

Get data:

```
1 def getData(data_file, skip_rows=0):
2
3     with open(data_file) as fh:
4         file_io = StringIO(fh.read().replace(',', '\t'))
5
6     # Define names and data types for sighting data
7     record_types = np.dtype([
8         ('vessel',str,1),           #00 - Vessel ID
9         ('dates',str,6),           #01 - Date
10        ('times',str,6),           #02 - Time (local?)
11        ('lat',float),             #03 - latitude dec
12        ('lon',float),             #04 - longitude dec -1
13        ('beafort',str,2),         #05 - beafort scale
14        ('weather',int),           #06 - weather code
15        ('visibility',int),        #07 - visibility code
16        ('effort_sec',float),       #08 - seconds on effort
17        ('effort_nmil',float),     #09 - n miles on effort
18        ('lat0',float),            #10 - lat of sight start
19        ('lon0',float),            #11 - lon of sight start
20        ('num_observers',int),     #12 - number of observers
21        ('species',str,6),         #13 - species codes
22        ('num_animals',int),       #14 - number observed
23        ('sighting',int),          #15 - Boolean sight code
24        ('rdist',float),           #16 - distance to sight
25        ('angle',float),           #17 - angel from ship

```

## GEOS SETUP - PATHFINDER

The following are a series of functions defined in the `Geosetup` package module `pathfinder` that can be used for importing NOAA's pathfinder dataset.

Import:

```
import numpy as np
from netCDF4 import Dataset
import sys, os
import math
```

Covert coordinates to index position:

```
def coord2idx(coord, deg_range, cell_size, limit_keyword):
    '''Round decimal degrees or minutes to a defined limit'''

    # check that coordinate is valid
    if (coord < -deg_range) or (coord > deg_range):
        print '\nBathymetric grid coordinate range incorrect. Exiting.\n'
        sys.exit()

    # Calculate index position from provided coordinate
    idx = (coord/cell_size)+(deg_range/cell_size/2)

    # Round index to integer value up or down depending on boundary
    if limit_keyword == 'min':
        idx = int(math.floor(idx))
    elif limit_keyword == 'max':
        idx = int(math.ceil(idx))
    else :
        print '\nCoordinate keyword invalid. Exiting.\n'
        sys.exit()

    # Calculate decimal coordinate at rounded index position
    new_coord = (idx - (deg_range/cell_size/2))*cell_size

    return new_coord, idx
```

Print summary output:

```
def summary(file_path):
    ''' Extract gebco bathymetry data summary. '''

    # Get Lat/Lon from first data file in list
    dataset = Dataset(file_path, 'r')

    cols, rows = dataset.variables["dimension"]
    grid_w_deg, grid_h_deg = dataset.variables["spacing"]
    min_lon, max_lon = dataset.variables["x_range"]
    min_lat, max_lat = dataset.variables["y_range"]
    min_z, max_z = dataset.variables["z_range"]
    z = dataset.variables["z"][:5]
```

```
dataset.close()

print '\nGebco Bathymetric Data Summary:'
print '-----'
print 'cols: %i rows: %i' % (cols, rows)
print 'grid width: %06.5f grid height: %06.5f' % (grid_w_deg, grid_h_deg)
print 'min_lon: %5.1f max_lon: %5.1f' % (min_lon, max_lon)
print 'min_lat: %5.1f max_lat: %5.1f' % (min_lat, max_lat)
print 'min_z: %i max_z: %i' % (min_z, max_z)
print 'First five z: ', z
```

getGebcoData:

```
def getGebcoData(file_path,min_lon,max_lon,min_lat,max_lat):
    '''Extract gebco bathymetric data from geographic bounds

    cell_size: decimal degree x & y dimension of grid cells
    The depth data is a 1-D array. Given its size, it is faster
    to use fancy indexing to extract the geographical subsection.
    '''
    dataset = Dataset(file_path,'r')
    cell_size = dataset.variables["spacing"][0]
    cols, rows = dataset.variables["dimension"]

    # Set lon (column) index and lat (row) index, retrieve adjusted coords
    min_lon, min_lon_idx = coord2idx(min_lon, 360, cell_size, 'min')
    max_lon, max_lon_idx = coord2idx(max_lon, 360, cell_size, 'max')
    min_lat, min_lat_idx = coord2idx(min_lat, 180, cell_size, 'min')
    max_lat, max_lat_idx = coord2idx(max_lat, 180, cell_size, 'max')

    # TODO check if incorrect to offset by one
    lon_range = (max_lon_idx - min_lon_idx) + 1
    lat_range = (max_lat_idx - min_lat_idx) + 1
    data_range = lon_range * lat_range

    zi = 0
    # Create zero array with the appropriate length for the data subset
    z = np.zeros(data_range)
    # Process number of rows for which data is being extracted
    for i in range((max_lat_idx - min_lat_idx)):
        # Pull row, then desired elements of that row into buffer
        tmp = (dataset.variables["z"][(i*cols):((i*cols)+cols)])[min_lon_idx:max_lon_idx]
        # Add each item in buffer sequentially to data array
        for j in tmp:
            z[zi] = j
            # Keep a count of what index position the next data point goes to
            zi += 1

    dataset.close()

    # Create latitude and longitude arrays
    lon_const = 360./cell_size/2
    lat_const = 180./cell_size/2
    lons = (np.asarray(range(lon_range)) + min_lon_idx - lon_const)*cell_size
    lats = (np.asarray(range(lat_range)) + min_lat_idx - lat_const)*cell_size
    lons, lats = np.meshgrid(lons,lats)
    lons = np.ravel(lons)
    lats = np.ravel(lats)

    # TODO remove
    print 'len_lons: ', lons.shape
    print 'len_lats: ', lats.shape
    print 'len_z: ', z.shape

    return lons, lats, z
```

Main Program:

```
if __name__ == '__main__':  
    # commandline usage  
    if len(sys.argv) < 2:  
        print >>sys.stderr, 'Usage:', sys.argv[0], '<data directory>\n'  
        sys.exit(1)  
  
    data_dir = sys.argv[1]  
    data_file = 'gridone.nc'  
  
    file_path = os.path.join(data_dir, data_file)  
  
    summary(file_path)  
  
    # getGebcoData(file_path, min_lon, max_lon, min_lat, max_lat):  
    lons, lats, z = getGebcoData(file_path, -20, 20, -20, 20)  
  
    print 'lons: ', lons[:]  
    print 'lats: ', lats[:]  
    print 'z: ', z[:]
```

## GEOSETUP - CORTAD

As described by Trond Kristiansen [on his blog](#) [7]. The following are methods developed by him to import data from NOAA's CoRTAD data series.

Imports:

```
import os, sys, datetime, string
import numpy as np
from netCDF4 import Dataset
import numpy.ma as ma
import matplotlib.pyplot as plt
from pylab import *
import mpl_util
```

Get CoRTAD Time:

```
1     def getCORTADtime():
2
3         #base="http://data.nodc.noaa.gov/thredds/dodsC/cortad/Version4/"
4         base='/media/data/storage02/asf-fellowship/data/CoRTAD/version4/'
5         file1="cortadv4_row00_col05.nc"
6         filename1=base+file1
7         cdf1=Dataset(filename1)
8
9         print "Time: Extrating timedata from openDAP: %s"%(filename1)
10
11        time=np.squeeze(cdf1.variables["time"][:])
12        cdf1.close()
13        return time
```

Open CoRTAD Files:

```
1     def openCoRTAD():
2         # TODO Generalize to accept dates and geobounds, data dir
3         """ Info on the different tiles used to identify a region is found here:
4         http://www.nodc.noaa.gov/SatelliteData/Cortad/TileMap.jpg"""
5         #base='/media/data/storage02/asf-fellowship/data/CoRTAD/version4/'
6         base= '/home/ryan/code/python/projects/asf/geosetup/data/cortad/'
7         # base="http://data.nodc.noaa.gov/thredds/dodsC/cortad/Version4/"
8
9         start_row = 00
10        start_col = 05
11        end_row = 01
12
13        file1="cortadv4_row00_col05.nc"
14        file2="cortadv4_row00_col06.nc"
15        file3="cortadv4_row00_col07.nc"
16        file4="cortadv4_row00_col08.nc"
17        file5="cortadv4_row00_col09.nc"
18        file6="cortadv4_row01_col05.nc"
19        file7="cortadv4_row01_col06.nc"
20        file8="cortadv4_row01_col07.nc"
```

```

21     file9="cortadv4_row01_col08.nc"
22     file10="cortadv4_row01_col09.nc"
23

3         main()
```

# GEOS SETUP - GLOB COLOUR

The following are methods from the `globcolour` module in the `Geosetup` package for importing chlorophyll a data from the GlobColour data series produced by ESA.

## 14.1 Importing Mapped L3m Data

Extract GlobColour chlorophyll data from netCDFs

```
1 import sys, os
2 from netCDF4 import Dataset
3 import numpy as np
4 import numpy.ma as ma
5 import isingrid as grid
6 import re
7 import csv
8 import datetime
9 from mpl_toolkits.basemap import Basemap
10 import matplotlib.pyplot as plt
```

Subset geospatial data (remove?):

```
1 def subset_geodata(max_lon, min_lon, max_lat, min_lat, lons, lats, values):
2     '''subset_geodata returns a subset of lat/lon/value data from defined
3     defined bounds in decimal degrees'''
4     subset_lons = lons[(lons<max_lon)&(lons>min_lon)&(lats<max_lat)&(lats>min_lat)]
5     subset_lats = lats[(lons<max_lon)&(lons>min_lon)&(lats<max_lat)&(lats>min_lat)]
6     subset_vals = values[(lons<max_lon)&(lons>min_lon)&(lats<max_lat)&(lats>min_lat)]
7     return subset_lons, subset_lats, subset_vals
```

Find nearest value in array, and return the index position of it:

```
1 def find_nearest(array, value):
2     '''
3     Returns index position of element nearest to given value
4     '''
5     idx = (np.abs(array-value)).argmin()
6     #return array[idx] # return value
7     return idx # return index
```

Get Mapped GlobColour Data:

```
1 def getMappedGlob(data_dir, min_lon, max_lon, min_lat, max_lat, data_time_start, data_time_end):
2     '''
3     Extracts subset of globcolour data based on lat/lon bounds and dates in the
4     iso format '2012-01-31'
5     '''
6
```

```

7      #TODO figure out if this is right
8      file_list = np.asarray(os.listdir(data_dir))
9      file_dates = np.asarray([datetime.datetime.strptime(re.split('[.]', filename)[1], '%Y%m%d')
10                             for filename in file_list])
11      data_files = file_list[(file_dates >= data_time_start) & (file_dates <= data_time_end)]
12
13      # Get Lat/Lon from first data file in list
14      dataset = Dataset(os.path.join(data_dir, file_list[0]), 'r')
15      lons = dataset.variables["lon"][:]
16      lats = dataset.variables["lat"][:]
17      vals_sum = np.zeros_like(dataset.variables["CHL1_mean"][:][:])
18      mask_sum = np.empty(np.shape(vals_sum), dtype=bool)
19      dataset.close()
20
21      # Create cumulative mask before averaging data
22      for data_file in data_files:
23          current_file = os.path.join(data_dir, data_file)
24          dataset = Dataset(current_file, 'r') # by default numpy masked array
25          mask = (dataset.variables["CHL1_mean"][:][:]).mask
26          mask_sum = mask + mask_sum
27
28      vals_sum.mask = mask_sum
29
30      # Get average of chlorophyl values from date range
31      file_count = 0
32      for data_file in data_files:
33          current_file = os.path.join(data_dir, data_file)
34          dataset = Dataset(current_file, 'r') # by default numpy masked array
35          vals = dataset.variables["CHL1_mean"][:][:]
36          vals.mask = mask_sum
37          vals_sum += vals
38          #TODO remove
39          #printstuff(vals, vals_sum, file_count)
40          file_count += 1
41          dataset.close()
42
43      vals_mean = vals/file_count #TODO simple average
44
45      # Mesh Lat/Lon the unravel to return lists
46      #TODO make mesh optional (i.e. return grid or lists)
47      lons_mesh, lats_mesh = np.meshgrid(lons, lats)
48      lons = np.ravel(lons_mesh)
49      lats = np.ravel(lats_mesh)
50
51      # Print Globcolour Information
52      print '\nChl-a Information'
53      print '-----'
54      print 'Start Date: ', data_time_start
55      print 'End Date: ', data_time_end
56      print 'Max Chl-a: ', np.amax(vals_mean)
57      print 'Min Chl-a: ', np.amin(vals_mean)
58
59      return lons, lats, vals_mean

```

### Main Program:

```

1      if __name__ == '__main__':
2
3          # commandline usage #
4          if len(sys.argv) < 2:
5              print >>sys.stderr, 'Usage:', sys.argv[0], '<data directory>\n'
6              sys.exit(1)
7
8          data_dir = sys.argv[1]
9
10         lons, lats, vals_mean = getMappedGlobcolour(data_dir, 0., 50., 30., 60., '2007-08-01', '2007-08-30')
11         print lons

```

## 14.2 Importing ISIN grid L3b Data

The following methods can be used to convert data in the ISIN grid format into latitude and longitude data, which is a Python translation of the R code that was posted on the following blog page:

<http://menugget.blogspot.com/2012/04/working-with-globcolour-data.html>

Import:

```

1     import numpy as np
2
3     '''
4     from: http://menugget.blogspot.no/2012/04/working-with-globcolour-data.html#more
5
6     This function is used converts ISIN grid information used by Globcolour to latitude
7     and longitude for a perfect sphere, as well as to construct associated polygons for use in mapping.
8
9     The raw Globcolour .nc files come with column and row pointers
10    as to the grid's location. For 4.63 km resolution data, this
11    translates to 4320 latitudinal rows with varying number of
12    associated longitudinal columns depending on the latitudinal
13    circumference.
14
15    Input must be either a vector of grid numbers ["grd"] or a dataframe
16    with column and row identifiers ["coord", e.g. columns in coord$col and
17    rows in coord$row]
18
19    When the argument "polygon=FALSE" (Default), the function will output
20    a dataframe object containing grid information (gridnumber["output$grd"],
21    column["output$col"], row["output$row"], longitude["output$lon"], and
22    latitude[output$lat])
23
24    If the argument "polygon=TRUE", then the output will be a list with
25    polygon shapes in a dataframe(longitudinal coordinates of corners
26    ["[[i]]$x"], latitudinal coordinates of corners ["[[i]]$y")
27    '''

```

Convert ISIN grid to Lat Lon Coordinates:

```

1     def isin_convert(grid = None, coord = None, polygons = False):
2
3         earth_radius = 6378.137 # TODO this was different in globcolour metadata
4         Nlat = 4320 # Number of latitudinal bands, globcolour default 4km resolution
5         pi = np.pi
6         circum = 2*pi*earth_radius # circumference of Earth at equator
7
8         lat_rows = np.arange(1,Nlat+1,1) # nparray of sequence 1 to Nlat
9
10        # circumfrance at equator / lat bin width:
11        # delta-radius, varies by how many parallels there are (Nlat)
12        dr = (pi*earth_radius)/Nlat
13        # angle increment between each parrallel:
14        # delta-phi, from equator to pole
15        dphi_lat = pi/Nlat
16
17        phi = -(pi/2)+(lat_rows*dphi_lat)-(dphi_lat/2) # nparray of angles
18        # calculate latitudal circumference of parallels:
19        p = circum*np.cos(phi) # np array of circ in __ (2*Pi*r)*cos(phi)
20        # number of lon rows, dimension = lat dimension at equ.
21        Nlon = np rint(p/dr) #round to nearest whole integer
22        dlon = p/Nlon # circumfrance / number of meridians
23        dphi_lon = (2*pi)/Nlon
24        Ntot = sum(Nlon)
25        lat = phi*(180/pi) # nparray of angles to radians
26
27        if (grid is not None):
28            # calculate coordinates

```

```
29     cum_Nlon = np.cumsum(Nlon)
30     # TODO the following doesn't work for array [1,2,3,4], matters?
31     grid_rows = np.asarray([np.amax(np.where(cum_Nlon < point)) for point in grid])
32     grid_cols = grid - cum_Nlon[grid_rows]
33     # calculate longitude and latitude

37
38     if (coord is not None):
39         #calculate coordinates
40         grid_rows = coord[:,0]
41         grid_cols = coord[:,1]
42         print grid_rows
43         print grid_cols
44         # calculate longitude and latitude
45         grid_lats = lat[grid_rows]
46         Nlon_rows = Nlon[grid_rows]
47         grid_lons = (360*(grid_cols-0.5)/Nlon_rows)-180
48         # calculate grid
49         cum_Nlon = np.cumsum(Nlon)
50         grid = cum_Nlon[grid_rows] + grid_cols # TODO check what this does
51         cum_Nlon = np.cumsum(Nlon)
52         return grid_lats, grid_lons
53     if (polygons is not None):
54         Nlon_rows = Nlon[grid_rows]
55         grid_width = 360/Nlon_rows
56         grid_height = 180/Nlat
57         # create list l to (number of elements in grid)
58         polys = range(0, len(grid))
59         xs = np.hstack([grid_lons[polys]-grid_width/2,
60                        grid_lons[polys]-grid_width/2,
61                        grid_lons[polys]+grid_width/2,
62                        grid_lons[polys]+grid_width/2])
63
64         ys = np.hstack([grid_lats[polys]-grid_height/2,
65                        grid_lats[polys]+grid_height/2,
66                        grid_lats[polys]+grid_height/2,
67                        grid_lats[polys]-grid_height/2])
68         #TODO check that what's retu
69         #         return xs,ys #np.vstack([xs,ys])
70
71     if (polygons is None):
72         array = np.vstack([grid, grid_cols, grid_rows, grid_lons, grid_lats])
```

## Main function:

```
1     if __name__ == "__main__":
2         grid = np.array([20,35,60,900])
3         print isin_convert(grid)
```

## GEOSETUP - GEBCO

The methods in the `gebco` module of the `Geosetup` package allow for importing of the GEBCO Bathymetric data provided by the British Oceanographic Data Centre.

Imports:

```
1 import numpy as np
2 from netCDF4 import Dataset
3 import sys, os
4 import math
```

Convert coordinates to index positions:

```
1 def coord2idx(coord, deg_range, cell_size, limit_keyword):
2     '''Round decimal degrees or minutes to a defined limit'''
3
4     # check that coordinate is valid
5     if (coord < -deg_range) or (coord > deg_range):
6         print '\nBathymetric grid coordinate range incorrect. Exiting.\n'
7         sys.exit()
8
9     # Calculate index position from provided coordinate
10    idx = (coord/cell_size)+(deg_range/cell_size/2)
11
12    # Round index to integer value up or down depending on boundary
13    if limit_keyword == 'min':
14        idx = int(math.floor(idx))
15    elif limit_keyword == 'max':
16        idx = int(math.ceil(idx))
17    else :
18        print '\nCoordinate keyword invalid. Exiting.\n'
19        sys.exit()
20
21    # Calculate decimal coordinate at rounded index position
22    new_coord = (idx - (deg_range/cell_size/2))*cell_size
23
24    return new_coord, idx
```

Print summary info:

```
1 def summary(file_path):
2     ''' Extract gebco bathymetry data summary. '''
3
4     # Get Lat/Lon from first data file in list
5     dataset = Dataset(file_path, 'r')
6
7     cols, rows = dataset.variables["dimension"]
8     grid_w_deg, grid_h_deg = dataset.variables["spacing"]
9     min_lon, max_lon = dataset.variables["x_range"]
10    min_lat, max_lat = dataset.variables["y_range"]
11    min_z, max_z = dataset.variables["z_range"]
12    z = dataset.variables["z"][:5]
```

```

13
14         dataset.close()
15
16     print '\nGEBCO Bathymetric Data Summary:'
17     print '-----'
18     print 'cols: %i rows: %i' % (cols, rows)
19     print 'grid width: %06.5f grid height: %06.5f' % (grid_w_deg, grid_h_deg)
20     print 'min_lon: %5.1f max_lon: %5.1f' % (min_lon, max_lon)
21     print 'min_lat: %5.1f max_lat: %5.1f' % (min_lat, max_lat)
22     print 'min_z: %i max_z: %i' % (min_z, max_z)
23     print 'First five z: ', z

```

## Get GEBCO data:

```

1     def getGEBCOData(file_path,min_lon,max_lon,min_lat,max_lat):
2         '''Extract gebco bathymetric data from geographic bounds
3
4             cell_size: decimal degree x & y dimension of grid cells
5             The depth data is a 1-D array. Given its size, it is faster
6             to use fancy indexing to extract the geographical subsection.
7         '''
8         dataset = Dataset(file_path,'r')
9         cell_size = dataset.variables["spacing"][0]
10        cols, rows = dataset.variables["dimension"]
11
12        # Set lon (column) index and lat (row) index, retrieve adjusted coords
13        min_lon, min_lon_idx = coord2idx(min_lon, 360, cell_size, 'min')
14        max_lon, max_lon_idx = coord2idx(max_lon, 360, cell_size, 'max')
15        min_lat, min_lat_idx = coord2idx(min_lat, 180, cell_size, 'min')
16        max_lat, max_lat_idx = coord2idx(max_lat, 180, cell_size, 'max')
17
18        # TODO remove
19        print 'min_lon_idx', min_lon_idx, 'min_lon', min_lon

```

## GEOSETUP - MAIN PROGRAM

The following is the main program script for the `Geosetup` package that will import data from a comma separated text file and automatically produce sea surface temperature, chlorophyll a, and bathymetry datasets bound by the geographic bounds of the data provided.

Import:

```
1     #!/usr/bin/env python
2
3     from mpl_toolkits.basemap import Basemap
4     import matplotlib.pyplot as plt
5     import numpy as np
6     import sys, os, errno
7     import re
8     import math
9     import datetime
10    import numpy.lib.recfunctions
11    import pyproj
12    from StringIO import StringIO
13    import geosetup.mpl_util
14    #!/TODO make module naming consistent
15    from geosetup.globcolour import globcolour
16    from geosetup.pathfinder import pathfinder
17    from geosetup.gebco import gebco
18    from geosetup.interpolate import invdistgis, invdist
19    from geosetup.interpolate.datainterp import geointerp
20    from geosetup.writefile import data2raster
21    from geosetup.sightsurvey import sightsurvey
22
23    # prevent creation of .pyc files
24    sys.dont_write_bytecode = True
