"Consumers' Willingness to Pay for Animal Welfare Attributes in Dairy Products:

## **Consumers' Willingness to Pay for Animal Welfare Attributes in Dairy Products: Evidence From Experimental Auctions** Levan Elbakidze<sup>1</sup>, Hao Li<sup>1</sup>, Rodolfo Nayga<sup>2</sup> <sup>1</sup> University of Idaho, Department of Agricultural Economics and Rural Sociology, <sup>2</sup> University of Arkansas, Department of Agricultural Economics and Agribusiness

#### Introduction

- Debates about animal welfare in agricultural production have been increasing (Norwood and Lusk, 2009). Animal rights groups advocate for improved animal care. Livestock industry tends to dismiss the arguments as emotional and lacking scientific basis. Numerous publications highlighting the debate between the two sides have surfaced including but not limited to the report by the Pew Commission on Industrial Farm Animal Production (2008) and consequent response from The American Veterinary Medical Association (2009).
- Rollin (2003) as well as FAO (2009) discusses several dimensions of animal welfare in dairy production. Examples are, early separation of calf and mother, heat stress (some farmers provide shade and cooling with sprinklers), ample space, waste removal, flooring that reduces slippage, comfortable bedding, grazing on pasture, etc.
- While political and legislative efforts are ongoing, it is important to understand and reflect the impact of ethical dimensions of production, like consistency of agricultural production practices with "animal welfare" considerations, on consumer demand (Frank, 2006)
- A handful of studies have addressed public perceptions (Lusk and Norwood, 2008) and willingness to pay for improved animal care in agricultural production using hypothetical choice experiments (Liljenstolpe, 2008; Carlsson et al. 2007).
- To the best of our knowledge there have been no other known published studies which estimate consumer willingness to pay (WTP) for animal welfare attributes in agricultural production using non-hypothetical experimental methods, and there have been no studies on consumer WTP for animal welfare attributes in dairy industry.

#### Objectives

- Estimate consumers' WTP for dairy products produced using practices consistent with "humane animal care" principles.
- Evaluate difference between two uniform price auction mechanisms (2nd price Vickrey auction and random Nth price Vickrey auction) and Open Ended Choice Experiments (OECE) in a non-hypothetical setting
- Evaluate the effect of information treatment on consumer behavior
- Estimate demand schedule, rather than a conventional WTP for 1 unit of a good, using OECE as well as Uniform Price Auctions
- Evaluate the effect of posted prices on participant behavior under uniform price auctions.
- Examine the effects of having multiple "bidding" rounds on participant behavior

#### **Experimental Design**

- All participants (218) were paid \$30 for participating
- Participants played for "Humane" Ice Cream, and "Humane" Cheese
- Conventional Ice Cream and Conventional Cheese were available for purchase after each experiment session at the going market prices (\$0.25/scoop of ice cream, and \$0.5 per cheese unit)
- Non-hypothetical experimental methods were used to elicit consumers' willingness to pay. Specifically, we used Uniform Price Vickrey Auctions (UPVA) and Open Ended Choice Experiments (OECE)
  - **UPVA**: In this mechanism, the participants submit bids for different quantities of the goods in five rounds. On the provided sheet they are asked to write their bids for each amount and submit at the end of each round. Total
  - of five rounds were played in the real auction. Two mechanisms of UVPA that were used in this study are: • 2<sup>nd</sup> price Vickrey Auction – Highest bidder is declared as the winner and pays the price equal to the second highest bid (List and Shogren, 1999; Knetsch and Tang, 2001; Corrigan and Rousu, 2006)
  - Random N<sup>th</sup> price Vickrey Auction Binding price is selected to be the randomly determined N<sup>th</sup> highest bid. Top N-1 bidders pay the binding price (Rousu et al. 2004; Shogren et al. 2001)
- **OECE**: In this mechanism, the participants are presented with several different price combinations and are asked to indicate how many units they would like to purchase at each of these prices. A binding price is selected randomly, and everyone is expected to purchase the amount they indicated for the binding price (Corrigan et al. 2009). One of the five rounds is selected as binding
- In each mechanism the binding product was randomly determined for each round.
- Each mechanism had informed and uninformed treatment groups

#### **Empirical Methods**

Following econometric techniques were used:

- UPVA: Tobit for 4<sup>th</sup> round data; and Random Effects Tobit for panel data
- OECE: Poisson, Negative Binomial, Zero Inflated Poisson, Zero Inflated Negative Binomial, for the 4th round data; and Random Effects Poisson and Random Effects Negative Binomial for the Panel data.

The preferred models for OECE were chosen by using Vuong test, for ZINB vs. NB, and ZIP vs. Poisson, an likelihood ratio test on Alpha=0 for over dispersion for Poisson vs. NB, and ZINB vs. ZIP. The tests results favored ZINB.

#### Conclusions

- test) and in Tobit regression.
- OECE, but not in Vickrey auctions.
- not on ice cream bids.
- There was no significant difference in male vs. female bids.
