Chemistry 1051 Intersession 2007
Midterm Exam 2

Name: $\qquad$ MUN \#: $\qquad$

## Dr. Peter Warburton

## READ THE FOLLOWING CAREFULLY!

1. This exam has 7 pages with 2 sections. SECTION A is comprised of longer answer questions and SECTION B is comprised of short answer questions. Ensure that this examination paper is complete, i.e. that all pages are present.
2. Failure to submit this paper in its entirety at the end of the examination may result in disqualification.
3. A Periodic Table and physical constants are provided. These are on the last page of the examination and may be detached for use during the examination.
4. Answer each question in the space provided. Should you require more space, use the back of the page and indicate clearly where this has been done.
5. When answering questions show all relevant formulae, all calculations, and justify all simplifying assumptions.
6. Correct units should be maintained in all steps of a calculation.
7. Numerical answers should be reported with the correct significant digits.

Do not write in the enclosed area below.

| Question | Value | Mark |
| :---: | :---: | :---: |
| A1 | 5 |  |
| A2 | 7 |  |
| A3 | 9 |  |
| Section B | 21 |  |
| Total | $\mathbf{4 2}$ |  |

## Section A <br> Longer Answer Questions <br> (21 Marks)

The value of each part of a question is given in the square brackets in the left margin beside each question.
[5] A1. What is the $\mathrm{K}_{\mathrm{a}}$ value at $25^{\circ} \mathrm{C}$ for propionic acid $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{COOH}\right)$ if the percent ionization of a 0.0040 M solution of propionic acid is $5.6 \%$ ?

|  | $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \leftrightarrows \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ |  |  |
| :--- | :---: | :---: | :---: |
| Initial | 0.0040 M | 0 M | 0 M |
| Change | $-x$ | $+x$ | $+x$ |
| Eqm | $0.0040 \mathrm{M}-x$ | $+x$ | $+x$ |

By the definition of percent ionization, we know that

$$
\begin{gathered}
\%_{\text {ion }}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {eqm }} /\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{COOH}\right]_{\text {initial }} \\
\text { Since }\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {eqm }}=x \text { this means } \\
x=\left(\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{COOH}\right]_{\text {initial }}\right)(\% \text { oion })=(0.0040 \mathrm{M})(5.6 \%)=0.00022_{4} \mathrm{M} \\
\mathrm{~K}_{\mathrm{a}}=\frac{\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{COO}\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\right.}{\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{COOH}\right]}=\frac{\mathrm{x}^{2}}{0.0040-\mathrm{x}}=\frac{\left(0.00022_{4}\right)^{2}}{0.0040-0.00022_{4}}=\frac{5.0_{2} \times 10^{-8}}{3.7_{6} \times 10^{-3}}=1.3_{3} \times 10^{-5}
\end{gathered}
$$

[7] A2. An equilibrium mixture at a particular temperature contains $0.310 \mathrm{M} \mathrm{CO}(\mathrm{g})$, $0.140 \mathrm{M} \mathrm{Cl}_{2}(\mathrm{~g})$ and $0.780 \mathrm{M} \mathrm{COCl}_{2}(\mathrm{~g})$ in a 2.00 L container. Calculate the number of moles of $\mathrm{Cl}_{2}(\mathrm{~g})$ which must be added to the equilibrium mixture in the 2.00 L flask to reduce the concentration of $\mathrm{CO}(\mathrm{g})$ to 0.250 M when equilibrium is re-established at the same temperature for the chemical system shown below:

$$
\mathrm{Cl}_{2}(\mathrm{~g})+\mathrm{CO}(\mathrm{~g}) \leftrightarrows \mathrm{COCl}_{2}(\mathrm{~g})
$$

For our original system at equilibrium

$$
\mathrm{K}_{\mathrm{c}}=\frac{\left[\mathrm{COCl}_{2}\right]}{\left[\mathrm{Cl}_{2}\right]\left[\mathrm{CO}_{2}\right]}=\frac{(0.780)}{(0.140)(0.310)}=18.0
$$

| (all in mol $\cdot \mathrm{L}^{-1}$ ) | $\mathrm{Cl}_{2}(\mathrm{~g})$ |  | $\mathrm{CO}(\mathrm{g})$ |
| :---: | :---: | :---: | :---: |
| Initial [] | $0.140+x$ | 0.310 | 0.780 |
| Change in [] | $-y$ | $-y$ | $+y$ |
| Equilibrium [] | $0.140+x-y$ | $0.310-y=0.250$ | $0.780+y$ |

We can see that $y=0.060 \mathrm{M}$

$$
\begin{gathered}
\mathrm{K}_{\mathrm{c}}=\frac{\left[\mathrm{COCl}_{2}\right]}{\left[\mathrm{Cl}_{2}\right][\mathrm{CO}]}=\frac{(0.780+\mathrm{y})}{(0.140+\mathrm{x}-\mathrm{y})(0.250)}=\frac{(0.780+0.060)}{(0.140+\mathrm{x}-0.060)(0.250)}=18.0 \\
\text { so } \frac{(0.840)}{(0.080+\mathrm{x})(0.250)}=18.0 \\
\text { so } 0.080+\mathrm{x}=\frac{(0.840)}{(18.0)(0.250)}=0.187 \quad \text { so } \quad \mathrm{x}=0.107 \mathrm{M}
\end{gathered}
$$

Which means since we have $2.00 L$ container we needed to add 0.214 mol of $\mathrm{Cl}_{2}$.
Out of interest, this question represents an application of Le Chatalier's principle. If we add $\mathrm{Cl}_{2}$ to the equilibrium mixture, the system will respond by trying to get rid of the added $\mathrm{Cl}_{2}$. The only way it can do this is by reacting some of the new $\mathrm{Cl}_{2}$ with CO , decreasing the amount of CO and increasing the $\mathrm{COCl}_{2}$ in the new equilibrium mixture.
[9] A3. The reaction

$$
\mathrm{SO}_{2} \mathrm{Cl}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g})
$$

has the equilibrium constant $\mathbf{K}_{\mathbf{c}}=\mathbf{0 . 0 1 1}$ at a certain temperature.
A 2.0 L flask starts with 0.30 mol of $\mathrm{SO}_{2}, 0.16 \mathrm{~mol}^{\text {of }} \mathrm{Cl}_{2}$, and 0.50 mol of $\mathrm{SO}_{2} \mathrm{Cl}_{2}$. Calculate the equilibrium concentrations of the gases.

If we start with a reaction quotient calculation in terms of concentration, we need the initial concentrations of the gases. Since concentration is number of moles divided by volume, the initial concentrations of the gases will be

$$
\begin{aligned}
& 0.15 \mathrm{~mol} \cdot \mathrm{~L}^{-1} \text { of } \mathrm{SO}_{2}, 0.080 \mathrm{~mol} \cdot \mathrm{~L}^{-1} \text { of } \mathrm{Cl}_{2} \text {, and } 0.25 \mathrm{~mol} \cdot \mathrm{~L}^{-1} \text { of } \mathrm{SO}_{2} \mathrm{Cl}_{2} \\
& \qquad \mathrm{Q}_{\mathrm{c}}=\frac{\left[\mathrm{SO}_{2} \llbracket \mathrm{SCl}_{2}\right]}{\left[\mathrm{SO}_{2} \mathrm{Cl}_{2}\right]}=\frac{(0.15)(0.080)}{(0.25)}=0.048>\mathrm{K}_{\mathrm{c}}
\end{aligned}
$$

Since $Q>K$, we expect to lose products and gain reactants, so the ICE table looks like

| (all in mol $\cdot \mathrm{L}^{-1}$ ) | $\mathrm{SO}_{2} \mathrm{Cl}_{2}(\mathrm{~g})$ | $\mathrm{SO}_{2}(\mathrm{~g})$ | $\mathrm{Cl}_{2}(\mathrm{~g})$ |
| :---: | :---: | :---: | :---: |
| Initial | 0.25 | 0.15 | 0.080 |
| Change | +x | -x | -x |
| Equilibrium | $0.25+\mathrm{x}$ | $0.15-\mathrm{x}$ | $0.080-\mathrm{x}$ |

$$
\mathrm{K}_{\mathrm{c}}=\frac{\left[\mathrm{SO}_{2}\left[\mathrm{SC}_{2}\right]\right.}{\left[\mathrm{SO}_{2} \mathrm{Cl}_{2}\right]}=\frac{(0.15-\mathrm{x})(0.080-\mathrm{x})}{(0.25+\mathrm{x})}=0.011
$$

Rearranging, we get

$$
\begin{aligned}
& 0.011(0.25+\mathrm{x})=(0.15-\mathrm{x})(0.080-\mathrm{x}) \\
& 0.0027_{5}+0.011 \mathrm{x}=0.012_{0}-0.23_{0} \mathrm{x}+\mathrm{x}^{2} \\
& \mathrm{x}^{2}-0.24_{1} \mathrm{x}+0.0092_{5}=0
\end{aligned}
$$

This is a quadratic equation of the form $a x^{2}+b x+c=0$, which has solutions given by

$$
\begin{aligned}
& \mathrm{x}=\frac{-\mathrm{b} \pm \sqrt{\mathrm{b}^{2}-4 \mathrm{ac}}}{2 \mathrm{a}} \text { so } \mathrm{x}=\frac{-\left(-0.24_{1}\right) \pm \sqrt{\left(-0.24_{1}\right)^{2}-4(1)\left(+0.0092_{5}\right)}}{2(1)} \\
& \mathrm{x}=\frac{\left(0.24_{1}\right)+\sqrt{(-0.241)^{2}-4(1)\left(+0.0092_{5}\right)}}{2} \text { or } \mathrm{x}=\frac{\left(0.24_{1}\right)-\sqrt{(-0.241)^{2}-4(1)\left(+0.0092_{5}\right)}}{2} \\
& \mathrm{x}=\frac{\left(0.24_{1}\right)+\sqrt{0.058_{08}-0.037}}{2} \text { or } \mathrm{x}=\frac{\left(0.24_{1}\right)-\sqrt{0.058_{08}-0.037}}{2} \\
& \mathrm{x}=\frac{\left(0.24_{1}\right)+\sqrt{0.021_{08}}}{2} \text { or } \mathrm{x}=\frac{\left(0.24_{1}\right)-\sqrt{0.021_{08}}}{2} \text { so } \mathrm{x}=\frac{\left(0.24_{1}\right)+0.14_{5}}{2} \text { or } \mathrm{x}=\frac{\left(0.24_{\mathrm{s}}\right)-0.14_{5}}{2} \\
& \mathrm{x}=\frac{0.38_{6}}{2} \text { or } \mathrm{x}=\frac{0.096}{2} \quad \text { so } \mathrm{x}=0.19_{3} \mathrm{~mol} \cdot \mathrm{~L}^{-1} \quad \text { or } \mathrm{x}=0.048_{0} \mathrm{~mol} \cdot \mathrm{~L}^{-1}
\end{aligned}
$$

If we choose $x=0.174 \mathrm{~mol} \cdot \mathrm{~L}^{-1}$ as the answer, then $\left[\mathrm{SO}_{2}\right]=0.15 \mathrm{~mol} \cdot \mathrm{~L}^{-1}-\left(0.193 \mathrm{~mol} \cdot \mathrm{~L}^{-1}\right)$ $=-0.043 \mathrm{~mol} \cdot \mathrm{~L}^{-1}$, which isn't physically possible. Therefore $x=0.048 \mathrm{~mol} \cdot \mathrm{~L}^{-1}$. This means our equilibrium concentrations are

$$
\begin{gathered}
{\left[\mathrm{SO}_{2} \mathrm{Cl}_{2}\right]=0.25 \mathrm{~mol} \cdot L^{-1}+\left(0.048 \mathrm{~mol} \cdot L^{-1}\right)=0.29_{8} \mathrm{~mol} \cdot \cdot^{-1}} \\
{\left[\mathrm{SO}_{2}\right]=0.15 \mathrm{~mol} \cdot L^{-1}-\left(0.048 \mathrm{~mol} \cdot \mathrm{~L}^{-1}\right)=0.10_{2} \mathrm{~mol} \cdot \mathrm{~L}^{-1}} \\
{\left[\mathrm{Cl}_{2}\right]=0.080 \mathrm{~mol} \cdot \mathrm{~L}^{-1}-\left(0.048 \mathrm{~mol} \cdot L^{-1}\right)=0.032 \mathrm{~mol} \cdot \mathrm{~L}^{-1} .}
\end{gathered}
$$

We should check our answer:

$$
\mathrm{K}_{\mathrm{c}}=\frac{\left[\mathrm{SO}_{2}\left[\mathrm{Cl}_{2}\right]\right.}{\left[\mathrm{SO}_{2} \mathrm{Cl}_{2}\right]}=\frac{(0.102)(0.032)}{(0.298)}=0.011
$$

This is the equilibrium constant we were given, within rounding errors, so we should have the right answer.

## Section B <br> Short Answer <br> (21 Marks)

The value of each part of a question is given in the square brackets in the left margin beside each question.
[1] B1. What is the chemical formula for "slaked lime"?

$$
\mathrm{Ca}(\mathrm{OH})_{2}
$$

[3] B2. Phosgene is formed from carbon monoxide and chlorine:

$$
\mathrm{CO}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g}) \leftrightarrows \mathrm{COCl}_{2}(\mathrm{~g}) \quad \Delta \mathrm{H}=-105 \mathrm{~kJ}
$$

Briefly explain whether the amount of phosgene increases, decreases or remains the same when an equilibrium system for the above reaction is disturbed by:
a) decreasing the volume.

Decreasing the volume increases the total pressure of the system. The system responds by trying to decrease the pressure by shifting towards the side with less moles of gas. For this reaction this is the products, so the amount of phosgene increases.
b) increasing the temperature.

Since the reaction is exothermic, increasing the temperature favours the reverse reaction (it's like increasing the concentration of the product "heat") and so the amount of phosgene decreases.
c) adding sulphur dioxide $\left(\mathrm{SO}_{2}\right)$ to the container. Sulphur dioxide reacts with chlorine to form $\mathrm{SO}_{2} \mathrm{Cl}_{2}$.

Since sulphur dioxide reacts with chlorine, it decreases the amount of chlorine available to be used in the first reaction. Decreasing the amount of a reactant shifts the reaction from right to left and the amount of phosgene decreases.
[1] B3. Xenon forms compounds with highly electronegative fluorine and oxygen. In these compounds the xenon often is found in one of four common oxidation states. Give two of these four oxidation states. Only the first two will be marked

$$
\text { The common oxidation states of xenon are }+2,+4,+6 \text { and }+8 \text {. }
$$

[1] B4. What is the structure of the oxoacid $\mathrm{H}_{2} \mathrm{SeO}_{3}$ [selenous acid]?

[2] B5. What are the definitions of a Brønstead-Lowry base and an Arrhenius base. Give an example of a Brønstead-Lowry base that IS NOT also an Arrhenius base.

A BL base is a proton acceptor. An Arrhenius base dissociates in water to give OH . $\mathrm{NH}_{3}$ is an example of $B L$ base while not being an Arrhenius base.
[2] B6. Suppose in a sealed container that two gas phase equilibria occur at the same time:

$$
\begin{array}{cl}
2 \mathrm{GeO}(\mathrm{~g})+\mathrm{W}_{2} \mathrm{O}_{6}(\mathrm{~g}) \leftrightarrows 2 \mathrm{GeWO}_{4}(\mathrm{~g}) & \mathrm{K}=7.0 \times 10^{3} \text { Reaction (1) } \\
\mathrm{GeO}(\mathrm{~g})+\mathrm{W}_{2} \mathrm{O}_{6}(\mathrm{~g}) \leftrightarrows \mathrm{GeW}_{2} \mathrm{O}_{7}(\mathrm{~g}) & \mathrm{K}=3.8 \times 10^{4} \text { Reaction (2) }
\end{array}
$$

What is the equilibrium constant for the following reaction?

$$
\mathrm{GeO}(\mathrm{~g})+\mathrm{GeW}_{2} \mathrm{O}_{7}(\mathrm{~g}) \leftrightarrows 2 \mathrm{GeWO}_{4}(\mathrm{~g}) \quad \text { Reaction (3) }
$$

When we add reactions (2) and (3) we get reaction (1). Adding together equilibria means we multiply equilibrium constants, so

$$
\begin{gathered}
K_{\odot}=K_{\odot} \times K_{\odot} \\
\text { so } K_{\odot}=K_{\odot} / K_{\odot}=7.0 \times 10^{3} / 3.8 \times 10^{4}=0.18
\end{gathered}
$$

[3] B7. What is the pH of a $0.080 \mathrm{~mol} \cdot \mathrm{~L}^{-1}$ solution of CaO at $25^{\circ} \mathrm{C}$ ?
Since CaO is an alkaline earth metal oxide, it is a strong base and will react with water completely such that

$$
\begin{gathered}
2[\mathrm{CaO}]_{i}=[\mathrm{OH}]_{e q} \\
\text { so }[\mathrm{OH}]_{e q}=2\left(0.080 \mathrm{~mol} \cdot \mathrm{~L}^{-1}\right)=0.16 \mathrm{~mol} \cdot \mathrm{~L}^{-1} \\
\text { and } p H=14.00-p O H=14.00-\left(-\log [\mathrm{OH}]_{e q}\right)=14.00-(-\log 0.16) \\
p H=14.00-0.80=13.20
\end{gathered}
$$

[2] B8. Hydrogen gas can react with sodium to form sodium hydride. Hydrogen gas can also be used in the formation of methanol by the reduction of carbon monoxide. What are the balanced equations for these two reactions?

$$
\begin{aligned}
2 \mathrm{Na}(\mathrm{~s})+\mathrm{H}_{2}(\mathrm{~g}) & \rightarrow 2 \mathrm{NaH}(\mathrm{~s}) \\
\mathrm{CO}(\mathrm{~g})+2 \mathrm{H}_{2}(\mathrm{~g}) & \rightarrow \mathrm{CH}_{3} \mathrm{OH}(\mathrm{~g})
\end{aligned}
$$

[3] B9. The reaction

$$
\mathrm{PCl}_{5}(\mathrm{~g}) \leftrightarrows \mathrm{PCl}_{3}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g})
$$

has the equilibrium constant $\mathrm{K}_{\mathrm{p}}=11.5$ at $300^{\circ} \mathrm{C}$. Calculate the equilibrium constant $\mathrm{K}_{\mathrm{c}}$ for this reaction at $300^{\circ} \mathrm{C}$.
$K_{p}=K_{c}(R T)^{\Delta n}$ where $\Delta n=($ moles of product gases - moles of reactant gasses)

$$
\begin{gathered}
K_{c}=K_{p} /(R T)^{(2-1)} \\
K_{c}=K_{p} /(R T)^{1} \\
K_{c}=K_{p} /(R T) \\
K_{c}=(11.5) /[(0.08206)(573)]
\end{gathered}
$$

note $T$ is in Kelvin and the specific value of $R$ used!

$$
K_{c}=0.244
$$

[1] B10. What is the characteristic colour of sodium in a Bunsen burner flame?

Yellow
[1] B11. What is the balanced equation for the production of liquid barium from the reaction of liquid barium oxide by liquid aluminum?

$$
3 \mathrm{BaO}(\mathrm{l})+2 \mathrm{Al}(\mathrm{l}) \rightarrow \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{~s})+3 \mathrm{Ba}(\mathrm{l})
$$

[1] B12. Which two noble gases are used in lasers?

## Kr and Xe

The End
