

Indiana Department of Natural Resources – Division of Forestry
State Forest Properties
Report of Continuous Forest Inventory (CFI)
Summary of years 1 - 5 (2008-2012)

Joey Gallion
Forest Resource Information/Forest Inventory Program Coordinator

FOREWARD

This report provides an overview of forest resource attributes for State Forest land managed by the IN DNR Division of Forestry based on findings from a continuous annual inventory conducted by the Forest Resource Information (FRI) Section of the IN DNR-Division of Forestry. The CFI inventory of Indiana DNR Division of Forestry State Forest property is based on a sample of 3,860 plots located randomly across those lands managed by the Division of Forestry (a total area of 155,725 acres), a sampling rate of approximately one plot for every 40 acres. Information in this report are gathered from quantitative and qualitative measurements that describe forest site attributes; stand characteristics; tree measurements on live and dead stems such as species, diameter, height, damage, tree quality; counts of regeneration; and estimates of growth, mortality, and removals. All estimates in this assessment are estimates of a population based on a statistical sample derived from the expansion of plot data and therefore may differ slightly from complete censuses of some populations (e.g., total acres). Given the multitude of estimates of forest resource attributes, they are organized in “core tables” (e.g., forest land area vs. live tree volumes) which are updated annually. This report is a summary of the initial five years of plot installation and data collection, which constitutes one entire cycle. Change attributes such as growth, removals, and mortality are acquired by other data sources than plot data as no plot re-measurement has occurred.

EXECUTIVE SUMMARY/HIGHLIGHTS

This is the first reported results of the newly established continuous forest inventory (CFI). The goal of the first five years was to install all of the plots within the CFI sample frame and produce baseline resource estimates. These baseline data/estimates will then be used as a monitoring baseline to compare to future remeasurement data in compilation of statistical change estimates (e.g., tree growth/mortality). Details of the results are discussed below, and tabular results can be found in the additional "Part B" report. Baseline resource estimates of state forest properties are:

- 155,725 total acres; 149,727 forested acres with the balance in non-forest (i.e. campgrounds) and water
- 95% of the forested acres are hardwoods

- 95% of the forested acres are sawlog-sized stands
- Forests contain 59.4 million live trees
- Sugar Maple trees and seedlings are more abundant than any other species
- 337.4 million cubic feet of total live tree volume
- 1.379 billion board feet (International ¼ inch) of sawlog volume
- White Oaks followed by Red Oaks are the species groups with the most sawlog volume
- Nearly half of the sawlog volume is considered grade 1 or 2
- Growth exceeds harvest by at least a 2:1 margin
- Multiflora rose, Japanese honeysuckle, and stiltgrass are the most common invasive species

FOREST COMPOSITION

Area

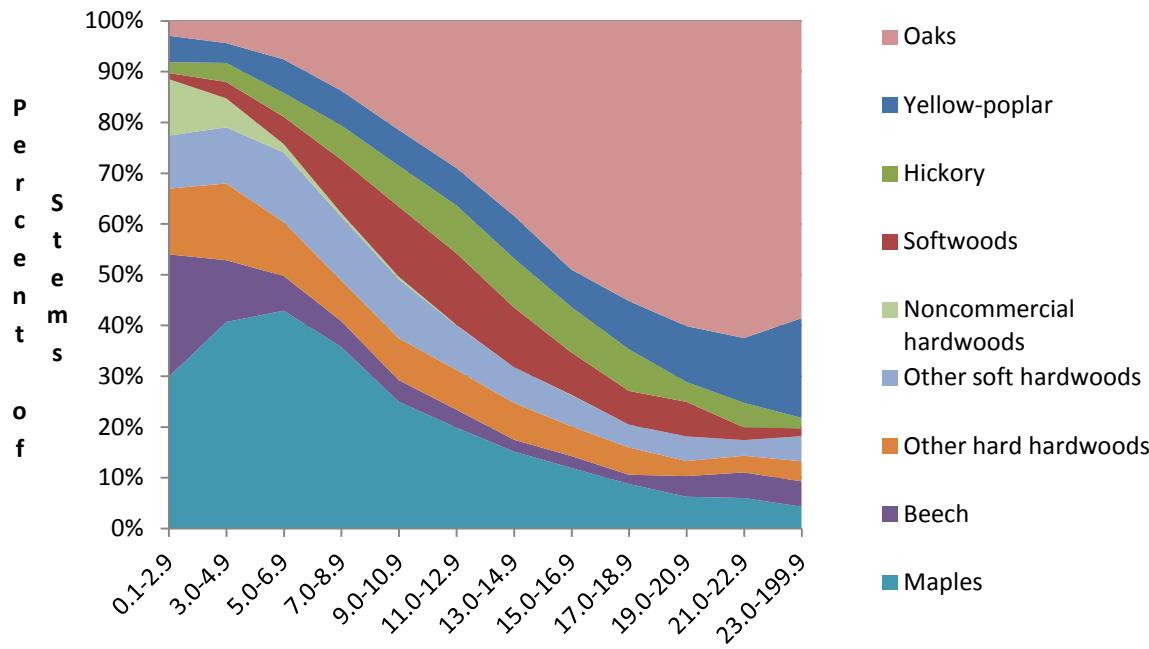

State Forest lands are comprised of approximately 155,725 acres located primarily in the southern 1/3 of Indiana. An estimated 149,727 of these acres are considered forestland (land considered stocked with trees or seedlings that is at minimum 1 acre in size and 120 feet in width), with the remaining ~6,000 acres being non-forest (open fields, campgrounds, right-of-ways, etc.), census water (bodies of water >5 acres and permanent rivers/streams), and non-census water (bodies of water <5 acres and small streams). Like most of Indiana's forests, state forests are predominantly hardwoods with 95% of the total forest area classified as hardwood forest types. The primary hardwood forest types were mixed upland hardwoods (49,881 acres, 33%), White Oak/Red Oak/Hickory (42,332 acres, 28%), and Chestnut Oak (10,975 acres, 7%) (Table 1). Ninety-five percent of the area was considered sawlog-sized stands (large diameter or 11.0" d.b.h. and greater), with the remainder classified as poles (medium diameter or 5.0-10.9" d.b.h.) and seedling/saplings (small diameter or 1.0-4.9" d.b.h.) (Table 1).

Number of Live Trees

It is estimated that there are 59.4 million live trees on state forest lands. In terms of the total number of live trees, Sugar Maple and Beech were the most abundant species at 13 million and 9.9 million trees respectively (Table 2). Over ½ of the number of trees were less than 3 inches d.b.h. with nearly 42.5 million being less than 5 inches d.b.h. An item of concern is the non-uniform distribution of the number of stems by diameter class for different species (Figure 1). In this sample, all Oak species combined represented about 3.3% of all saplings 1 inch to less than 5 inches d.b.h. The lack of Oak seedlings/saplings and abundance of Maple seedlings/saplings suggests a future decline of Oak/Hickory forest types as mature stands senesce.

Figure 1

Number of Trees by Species and Diameter Class

Volume of All Live Trees

The net volume of all live trees, which includes growing stock, rough, and rotten trees, 5" d.b.h. and above was 337.4 million cubic feet. Hardwoods constituted 313.0 million cuft or 93%. Oaks made up 145.8 million cuft or 43%, Yellow Poplar was 46.5 million cuft or 14%, Maples were 45.1 million cuft or 13%, and Hickories were 22.4 million cuft or 7% of the total volume (Table 3). Approximately 46.5 million cuft or 14% of the volume is in pole-sized trees (trees <11" d.b.h.) with the remainder being sawlog-sized (11" and greater d.b.h.). 63.3 million cuft or 19% is 23" or greater d.b.h. (Table 3). It was estimated that 327.5 million cuft of the total volume was in growing stock trees, with the remainder in rough cull and rotten cull trees. These volumes are presented in cubic feet because board foot volume estimates are only calculated on sawtimber-sized trees (hardwoods 11" d.b.h. and greater, softwoods 9" d.b.h. and greater).

Volume of Sawtimber-sized Trees

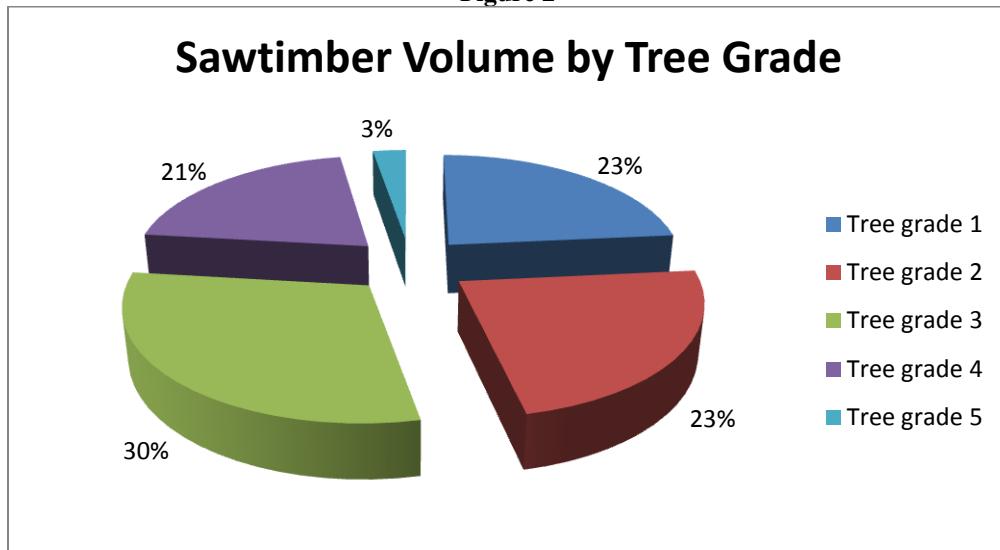

The total net sawtimber volume was 1.379 billion board feet International 1/4 inch scale. The White Oak group (mainly White and Chestnut Oak) was the largest species group with 408.7 million board feet (MMBF) or 30%, with the Red Oak group (mainly Northern Red and Black Oak) second with 238.2 MMBF or 17%. Yellow Poplar, Maples, Hickories, Beech, and Ash were the other major hardwood species groups ranked by sawlog volume with 218.1, 126.1, 93.7, 45.3, and 35.0 MMBF respectively (Table 4).

Grade of Sawtimber-sized Trees

Trees are graded using the Forest Service tree grading system. It grades the best 12' section in the butt 16' for hardwoods. Grade 1 must yield 10' clear of defects, grade 2 must yield 8' clear, grade 3 must yield 6' clear,

grade 4 must only be sound (tie grade) and grade 5 has a non-gradable butt log (due to form or rot) but has a gradable upper log (above the butt 16' log). It was estimated that 324.0 MMBF of the total net sawtimber volume was grade 1 and 319.9 and 415.5 MMBF in grades 2 and 3 respectively (Figure 2). Over 98% of the sawtimber volume of trees had 0-10% cull deductions.

Figure 2

CHANGE ATTRIBUTES AND ANCILLARY DATA ITEMS

Growth, Removals, and Mortality

We are beginning to re-measure plots in 2013. The uncertainty associated with our estimates of change will sequentially decrease as each year's annual remeasurement is added to the sample until all CFI plots have been remeasured. Until we have sufficient re-measured tree data for change estimates with an acceptable level of uncertainty, we will rely on FIA change estimates for our state forest properties. Using a query to select only plots sampled on state forest properties, the USFS Forest Inventory and Analysis (FIA) Program estimates that total annual growth on sawtimber is 40.4 MMBF which is 259 BF/ac/yr. In comparison, a 2005 system-wide inventory of all state forest properties estimated annual growth of sawtimber was 24.8 MMBF or 167 BF/acre/yr.

Records for the previous 10 years indicate that state forests have harvested an average 9.5 MMBF, or 12.1 MMBF per year on average for the past 5 years. Both of these removal or harvest estimates are well below either of the given growth estimates, suggesting that forests are being managed sustainably.

As with growth, when we re-measure our plots we will begin to estimate mortality as well (trees alive at time 1, but dead at time 2). Trees already dead were assessed (see the section below labeled standing dead trees) but we are unable to determine when these trees died (i.e., statistical censoring). Using statewide estimates from FIA data, we expect average annual mortality (volume estimates) at about 1%/year of total live tree volume.

Standing Dead Trees

There were an estimated 1.7 million standing dead trees 5" d.b.h. and greater. The individual species with the largest number of standing dead trees was Sassafras with 324 thousand standing dead trees. Virginia Pine was second with 185 thousand standing dead trees with White Oak and Chestnut Oak following with 170 and 153 thousand standing dead trees respectively (Table 5). As with the number of live trees, the number of standing dead trees decreased as the diameter increased. Of the 1.7 million standing dead trees, 952 thousand had a diameter from 5-9" d.b.h., 539 thousand were from 9-15" d.b.h., 142 thousand were from 15-19" d.b.h., and the remaining 80 thousand were 19" d.b.h. and greater (Table 5). For comparison, estimates made from stand-exam inventories from 2007-2010 showed very similar numbers...11.4 standing dead trees /acre (CFI data 11.4) for d.b.h. >5"; 5.3 standing dead trees /acre (CFI data 5.1) for d.b.h. >9"; and 0.57 standing dead trees /acre (CFI data 0.53) for d.b.h.>19". Standing dead trees were categorized in their decay process with a gradient code of 1-5...one being recent mortality and five having an extreme lack of structural integrity due to decay processes (see descriptors in table 6). It was found that 17% of standing dead trees were decay class 1, 16% as decay class 2, 31% as decay class 3, 28% as decay class 4, and the remaining 8% as decay class 5 (Table 6).

Cavity Trees

Of the 16.9 million live trees 5" d.b.h. and greater on the state forests, it is estimated that 1.2 million (7%) have a cavity present. A cavity is defined as a hole present on the tree at least 1" by 1" in size. Of the trees with cavities present, 52% were found on trees with diameters from 5-11" d.b.h., 35% from 11-19" d.b.h., and 13% 19" d.b.h. and greater (Table 7).

SUMMARY

The establishment of a statistically rigorous forest resource monitoring program modeled after many aspects of the Nation's forest inventory program (FIA) on Indiana's state forests is already yielding a baseline of resource information. Estimates from this baseline compare favorable to prior estimates available from the FIA program and previous inventories conducted on state forest properties. As estimates of state forest land resource attributes were either sampled at a lower plot intensity (FIA) or using inconsistent methodologies (stand-exams), estimates from Indiana's state forest land CFI program may be considered as a superior baseline.

Change estimates will become available in the future as a sufficient number of plots are remeasured to provide reliable estimates. The CFI system was not designed to produce change estimates until plots are re-measured (beginning in 2013 with 20% measured annually). Until a sufficient number of CFI plots are remeasured we will primarily rely on FIA data from plots on state forest lands for change estimates.

Even if all CFI plots are remeasured for change estimates, it is expected that the uncertainty associated with estimates of harvest will be relatively high as harvest is often only observed on a minority of plots compared to growth. We will always augment this removal data with data from our timber sales and strive to better correlate and reconcile differences between the inventory data and the sales data.

INVENTORY METHODS AND TECHNIQUES

In order to have a better understanding of Indiana's public forests, to assist in providing public disclosure for forest management, and with third party certification from SFI and FSC in mind, Indiana DNR Division of

Forestry began designing a Continuous Forest Inventory (CFI) system in 2007. The USDA Forest Service Forest Inventory and Analysis (FIA) program was chosen to mirror for several reasons. The IN DNR began to negotiate with FIA to build the CFI system to meet the certification audit requirements and yet coincide with the existing FIA standards. A unique system was designed and implementation of plot establishment on the forest began in calendar year 2008. The plots were spaced such that approximately an equal number of plots per year per state forest property (an annual panel) would be completed. Annually these panels can stand alone as an independent survey and therefore some results of significant value can be analyzed and reported on an annual basis.

Quality Assurance/Quality Control

The CFI program is the key program that provides the information needed to assess the status and trends of the IN DNR-Division of Forestry's managed forest lands. The goal of the CFI is to assure the production of complete, accurate and unbiased forest information of known quality. Specific measurement quality objectives (MQO) for precision are designed to provide a window of performance that we are striving to achieve for every field measurement (quality assurance or QA). Quality control (QC) procedures include direct feedback to field staff to provide continual real time assessment and improvements or refinements of field staff performance. These data quality goals were adapted from the USFS FIA program goals which were developed from knowledge of measurement processes in forestry and forest ecology.

At the heart of CFI quality is extensive staff training and expertise. Field staff meets minimum forest inventory requirements of a forestry education and background. In addition, each field staff member begins with an extensive on-the-job training program. Once the field staff member has a comfort level for what is expected of them, they begin production data collection on their own.

To quantify and evaluate how the field staff is performing, a second measurement (quality check) taken on a sample of completed field plots is performed by a trained and certified QA staff. This technique is done blindly, or without the production crew data on hand, and then the two sets of data are compared, analyzed, and scored to the given MQO standards. Three percent of the plots are pre-selected and considered mandatory quality check plots. The field staff does not have knowledge of which plots are mandatory checks. Field staff turn in completed data at given time intervals, and if no mandatory check plots are in that batch of production plots, then a random plot (non-mandatory) is picked to perform a quality check so that timely feedback can continuously be provided to the production field staff.

Each data measured in the field has an associated MQO for precision. This is an assigned tolerance or acceptable level of measurement error, and measure the ability of field staff to make repeatable measurements or observations within the assigned tolerances. In the analysis of QA data, an observation is within tolerance when the difference between the production field staff data and the quality check data do not exceed the assigned tolerance or MQO for that data element. For some data elements, the tolerance is "no error," thus only observations that are identical are within tolerance. For example, the tolerance for measurement of tree DBH is +/- 0.1 inch for each 20.0 inches of diameter of a live tree with the MQO for DBH set at 95%. The quality of the data is evaluated by comparing the desired rate of differences within tolerance (as a percent of observations) to the MQO. In the example above, the objective for DBH would be that 95% or more of the DBH observations are within +/- 0.1 inch for each 20.0 inches of diameter for all trees measured by both production field staff and QA staff.

Analysis of this QA dataset assures two things for the program: 1) a measurement of the accuracy of the data being collected and 2) an indicator of future training needs and refinement of the production field staff. With continuous program monitoring and productive feedback to field staff, the QAQC portion of the CFI program should continually improve the quality of the data over time.

Field Production Protocols

With the annual inventory system, about one-fifth of all field plots are measured each year. After 5 years, an entire inventory cycle is completed. After the first 5 years, results can be analyzed and reports created as a moving 5-year average. For example, Indiana CFI will be able to generate a report based on inventory results for 2008 through 2012 or for 2010 through 2014.

Field plots of the inventory consist of installing and measuring of the annual sample of field plots (panel) on each state forest. It was determined for desired CFI precision standards that the sampling intensity would be one plot for approximately every 40 acres. For efficiency, it was also determined that an entire compartment of a state forest property would be established and measured within the same panel. INCFI used the FIA non-overlapping hexagonal method to assist with establishing plot locations using Arc Map.

Field crews measure vegetation on plots based on FIA standards and protocols with few exceptions. Instead of the four subplot design that FIA uses, Indiana CFI only uses one 24-foot-radius ($1/24^{\text{th}}$ acre) circular subplot with the offset 6.8-foot-radius ($1/300^{\text{th}}$ acre) microplot. Trees with a d.b.h. 5 inches and larger are measured on the 24-foot-radius circular subplot. All trees 1 inch d.b.h. and larger are measured on the 6.8-foot-radius circular microplot located 12 feet east of the center of the subplot. Both tree and forest measurements are collected. Some measurements include:

- General stand characteristics such as forest type, stand size and age, slope and aspect, and any recent disturbances
- Tree species, diameter, several different heights, damage, amount of rotten or missing wood, crown measurements, and tree quality
- Counts of tree regeneration
- Presence of identified invasive plants

Specific field protocols can be found in the Indiana CFI Field Data Collection Procedures for Plots Field Manual (internal document). With few exceptions, the FIA field manual (version 4.0) will suffice and is readily available online at http://www.fia.fs.fed.us/library/field-guides-methods-proc/docs/core_ver_4-0_10_2007_p2.pdf.

Estimation Errors or Quality of the Estimates

The four primary sources of error common to all sample-based estimates are sampling, measurement, prediction, and non-response error. For each of these sources of error, a definition within the context of the CFI inventory is provided along with a discussion of methods used to quantify and reduce this error.

Sampling Error

The process of sampling (selecting a random subset of a population and calculating estimates from this subset) causes estimates to contain error they would not have if every member of the population had been observed and

included in the estimate. The CFI inventory of Indiana DNR Division of Forestry State Forest property is based on a sample of 3,860 plots located randomly across those lands managed by the Division of Forestry (a total area of 155,725 acres), a sampling rate of approximately one plot for every 40 acres. Along with every estimate is an associated sampling error that is typically expressed as a percentage of the estimated value but that can also be expressed in the same units as the estimate or as a confidence interval (the estimated value plus or minus the sampling error). This sampling error is the primary measure of the reliability of an estimate. A sampling error can be interpreted to mean that the chances are two out of three that had a 100-percent inventory been taken using these methods, the results would have been within the limits indicated (i.e., 67-percent confidence interval).

The sampling errors for State-level estimates of the major attributes presented in this report are shown in the Part B tabular data report. The estimators used by CFI are unbiased under the assumptions that the sample plots are a random sample of the total population and the observed value for any plot is the true value for that plot. Deviations from these basic assumptions are not reflected in the computation of sampling errors. The following sections on measurement, prediction, and nonresponsive error address possible departures from these basic assumptions.

Measurement Error

Errors associated with the methods and instruments used to observe and record the sample attributes are called measurement errors. On CFI plots, attributes such as the diameter and height of a tree are measured with different instruments, and other attributes such as species and crown class are observed without the aid of an instrument. On a typical CFI plot, 6 to 12 trees are observed with 15 to 20 attributes recorded on each tree. In addition, many attributes that describe the plot and conditions on the plot are observed. Errors in any of these observations affect the quality of the estimates. If a measurement is biased (such as tree diameter consistently taken at an incorrect place on the tree), then the estimates that use this observation (such as volume) will reflect this bias. Even if measurements are unbiased, high levels of random error in the measurements will add to the total random error of the estimation process.

To ensure that all CFI observations are made to the highest standards possible, a regular program of quality assurance and quality control is an integral part of all CFI data collection efforts, which was described above.

Prediction Error

Errors associated with using mathematical models (such as volume models) to provide observations of the attributes of interest based on sample attributes are referred to as prediction errors. Area, number of trees, volume, biomass, growth, removals, and mortality are the primary attributes of interest presented in this report. Area and number of trees estimates are based on direct observation and do not involve the use of prediction models; however, CFI estimates of volume, biomass, growth, removals, and mortality use model-based predictions in the estimation process. Models are used to predict volume and biomass estimates of individual tree volumes. In the future, change estimates such as growth, mortality, and removals will be based on these model-based predictions of volume from both the future plot re-measurements and the measurements taken in this first inventory.

Users of CFI estimates should be aware of the possible prediction errors in CFI estimates. In comparing CFI estimates to other data sources, users need to be aware of the prediction models used in both estimates. If both estimates are based on the same prediction models with matching fitted parameter values, then the prediction

bias of one estimate should cancel out that of the other estimate. If the estimates are based on different prediction models, then the user should be aware of the prediction error of both models.

Non-response Error

Non-response error refers to the error caused by not being able to observe some of the elements in the sample. In CFI, non-response occurs when crews are unable to measure a plot (or a portion of a plot) at a selected location. Non-response falls into the following three classes:

Denied access – Entire plots or portions of plots where the field crew is unable to obtain permission from the landowner and is therefore unable to measure the trees on the plot. This is not applicable in the CFI system on state forest properties, but could apply to the CFI system on the classified forest program.

Hazardous/inaccessible – Entire plots or portions of plots where the conditions present prevent a crew from safely getting to the plot or measuring the trees on the plot.

Other – Plots where the field crew is unable to obtain a valid measurement for a variety of reasons other than those stated above.

Non-response has two effects on the sample. First, it reduces the sample size. The reduced sample size is reflected in the sampling errors discussed in that section. Second, non-response can bias the estimates if the portion of the population not being sampled differs from the portion being sampled. Fortunately, in CFI, unlike many survey samples, non-response rates are relatively low. The non-response plots in this inventory were not permanently removed from the CFI system of plots. In future inventories we will again attempt to measure these plots. At that time we may be able to obtain permission to access these plots (for the classified forest system), the hazardous conditions may have changed, or other circumstances that caused us to not measure plots could be different.

Data Management

This collected data is then imported, housed, and processed using a sophisticated Oracle database system. This Oracle system consists of three different but linked databases: MIDAS, NIMS and FIADB. Midas is the pre-field database and historical data housing unit. NIMS is the post-field housing and processing database. FIADB is the database housing the presentation tables. So this Oracle system not only houses the data but also processes and readies the data for distribution. “Processing” the data combines certain measurements to determine some calculated estimates (e.g. using tree diameter, tree height, site index measurements, tree species, etc. to estimate tree volume using a volume equation).

Distribution is accomplished by eventually loading the post-processed data (FIADB tables) into a customized Access database that is very similar in functionality to the USFS FIA EVALIDator online tool. This Access database is used to assist with the analysis and interpretation of data. One can create customized tables with error estimates using this EVALIDator Access database.

Oracle processing protocols are documented as well (several internal documents). Most protocols are scripts written in sequel programming code or are instructions for the processing of the data and are intended for the database manager or advanced user only. An Access EVALIDator User Guide was created (beta version – work in progress) with the intent of being used as a reference guide after a training session of how to use EVALIDator has been attended.

PART B

List of Estimate Tables

Area

Table 1. — Area of forest land, in acres, by forest type and stand-size class, Indiana State Forests 2008-2012

Table 2. — Area of forest land, in acres, by forest type and stand age, Indiana State Forests 2008-2012

Table 3. — Area of forest land, in acres, by state forest and forest type, Indiana State Forests 2008-2012

Table 4. — Area of forest land, in acres, by state forest and stand-size class, Indiana State Forests 2008-2012

Table 5. — Area of forest land, in acres, by state forest and stand age, Indiana State Forests 2008-2012

Table 6. — Area of forest land, in acres, by state forest and site productivity class, Indiana State Forests 2008-2012

Table 7. — Area of forest land, in acres, by state forest and site index, Indiana State Forests 2008-2012

Number of Trees

Table 10.—Number of live trees on forest land by species and diameter class, Indiana State Forests 2008-2012

Table 11. — Number of live trees on forest land by species group and diameter class, Indiana State Forests 2008-2012

Table 12. — Number of standing dead trees (at least 5 inch d.b.h.) on forest land by species and diameter class, Indiana State Forests 2008-2012

Table 13. — Number of standing dead trees (at least 5 inch d.b.h.) on forest land by decay code and diameter class, Indiana State Forests 2008-2012

Table 14. — Number of live trees on forest land by cavity present and diameter class, Indiana State Forests 2008-2012

Volume of Trees – All Live

Table 20. — Net volume of live trees (at least 5 inches d.b.h.), in cubic feet, on forest land by species and diameter class, Indiana State Forests 2008-2012

Table 21. — Net volume of live trees (at least 5 inches d.b.h.), in cubic feet, on forest land by state forest and major species group, Indiana State Forests 2008-2012

Table 22. — Net volume of live trees (at least 5 inches d.b.h.), in cubic feet, on forest land by state forest and species group, Indiana State Forests 2008-2012

Table 23. — Net volume of live trees (at least 5 inches d.b.h.), in cubic feet, on forest land by tree class and diameter class, Indiana State Forests 2008-2012

Volume of Trees – Sawtimber

Table 30. — Net volume of sawtimber trees (International 1/4 inch rule), in board feet, on forest land by species and diameter class, Indiana State Forests 2008-2012

Table 31. — Net volume of sawtimber trees (International 1/4 inch rule), in board feet, on forest land by species group and diameter class, Indiana State Forests 2008-2012

Table 32. — Net volume of sawtimber trees (International 1/4 inch rule), in board feet, on forest land by tree grade and cull proportion, Indiana State Forests 2008-2012

*All tables contain forest attribute estimates for Indiana State Forest properties for measurements taken from 2008 to 2012, except where indicated

**Gaps in enumeration of tables are placeholders for future tables such as forest health indicator population estimates (e.g., downed woody material)

Table 1. — Area of forest land, in acres, by forest type and stand-size class, Indiana State Forests 2008 - 2012

Estimate: Area of forestland(acres)

Sampling Error percent: Area of forestland(acres)

Forest type	Stand-size	Large diameter	Medium diameter	Small diameter	Nonstocked
