

# Introduction by Examples

- Optical Character Recognition (OCR),
- Skin Detection based on pixel color,
- Texture classification,
- Speech recognition,
- Email Spam Detection.

2

## **Texture Classification**

Other application:

- Industrial surface inspection for defects,
- biomedical surface inspection for disease,

23

• ground classification of satellite or aerial imagery,.....

### **Texture Features**

To describe a texture, we can use as feature a mathematical measure of:

25

26

- fine or coarse ?
- smooth or rough ?
- homogeneous or inhomogeneous ?
- spatial structure, orientation,
- contrast, etc.

## **Texture Features**

A major problem is that textures in the real world are often not uniform, due to changes in orientation, scale or other visual appearance. Hence the features must be invariant to those variations.

# Texture feature 2: Second Order Stat.<sup>29</sup>

Example: second order histogram

$$hh(I_1, I_2, d, \Phi) = \begin{cases} P(I(m, n) = I_1, I(m \pm d, n) = I_2) & \text{for } \Phi = 0^{\circ} \\ P(I(m, n) = I_1, I(m \pm d, n \mp d) = I_2) & \text{for } \Phi = 45^{\circ} \\ P(I(m, n) = I_1, I(m, n \mp d) = I_2) & \text{for } \Phi = 90^{\circ} \\ P(I(m, n) = I_1, I(m \pm d, n \pm d) = I_2) & \text{for } \Phi = 135^{\circ} \end{cases}$$

Second order statistics may be used to represent smoothness, contrast, coarseness, regularity and other measurement that do not have a physical interpretation but a good discrimination power.

## Essence of Pattern Recognition

In Pattern Recognition, there are *many* classifiers.

So far there is no automated optimal classifier selection!

37

38

It depends on the *distribution* of the feature vectors in the feature space.

As this distribution is in general *inaccessible*, the practitioner must *assume* one.

The *accuracy* and the *efficiency* of the system will depend on this choice.

The other choice of the practitioner, which is not independent of the first one, is the one of the *features*.

### **Essence of Pattern Recognition**

Good features:

- have a simple distribution, that can be discriminated by simple and efficient classifiers.
- are invariant to transformations of the data present in the training set which are unrelated to the classification problem.

#### Conclusions

We have seen several examples of pattern recognition problems.

з۵

40

The two major questions of the design of a pattern recognition application are:

- 1. Which feature to use ?
- 2. Which *classifier* to use ?

The *feature* to be used depends heavily on the problem: feature for texture classification are not the same as those for OCR.

## Conclusions

However, the *classifier* used may be the same: Usually, a feature is a vector, any classifier taking vectorized input may be applied on OCR, texture classification, etc.

The choice of the classifier depends on the distribution of the training feature vectors in the feature space.
